Abstract: We report on high-pressure synchrotron X-ray diffraction measurements on Ni$_3$V$_2$O$_8$ at room-temperature up to 23 GPa. According to this study, the ambient-pressure orthorhombic structure remains stable up to the highest pressure reached in the experiments. We have also obtained the pressure dependence of the unit-cell parameters, which reveals an anisotropic compression behavior. In addition, a room-temperature pressure–volume third-order Birch–Murnaghan equation of state has been obtained with parameters: $V_0 = 555.7(2)$ Å$^3$, $K_0 = 139(3)$ GPa, and $K_0'' = 4.4(3)$. According to this result, Ni$_3$V$_2$O$_8$ is the least compressible kagome-type vanadate. The changes of the crystal structure under compression have been related to the presence of a chain of edge-sharing NiO$_6$ octahedral units forming kagome staircases interconnected by VO$_4$ rigid tetrahedral units. The reported results are discussed in comparison with high-pressure X-ray diffraction results from isostructural Zn$_3$V$_2$O$_8$ and density-functional theory calculations on several isostructural vanadates.

Keywords: vanadate; kagome compound; high pressure; X-ray diffraction; equation of state

1. Introduction

Metal orthovanadates with formula M$_3$V$_2$O$_8$, where M is a divalent metal, have been the focus of research in recent years, mainly because of their optical, dielectric, and magnetic properties [1–4]. These properties make the M$_3$V$_2$O$_8$ family of compounds useful in several technological applications, from photocatalytic water splitting [3] to light-emitting diodes [5] and ion batteries [6]. In addition, compounds such as Co$_3$V$_2$O$_8$ and Ni$_3$V$_2$O$_8$ have very interesting magnetic and ferroelastic properties [2], which are intimately related to the presence of kagome staircase two-dimensional (2D) magnetic layers [2].

M$_3$V$_2$O$_8$ compounds are also intriguing from a crystallographic perspective [7,8]. They share a particular type of crystal structure, which is shown schematically in Figure 1. The structure is orthorhombic (space group Cmca, No. 64) with eight formula units per unit cell. In the crystal structure, the M atoms are octahedrally coordinated by oxygen atoms (see Figure 1a). In particular, the MO$_6$ octahedral units exhibit an edge-sharing pattern, forming a quasi-planar kagome staircase (see Figure 1b), which, in the case of Ni$_3$V$_2$O$_8$, results in inequivalent super-exchange interactions within the magnetic lattice [9]. Consequently, an anisotropic magnetic coupling develops in the stair-like kagome layers, leading to the emergence of multiple temperature-induced magnetic phase transitions [9]. The kagome staircases are separated by VO$_4$ tetrahedral units, giving the M$_3$V$_2$O$_8$ family of compounds a pseudo-two-dimensional layered characteristic, which, as discussed below, leads to an anisotropic compressional behavior when an external pressure is applied.
AVO₄ orthovanadates, where A is a trivalent atom, have been extensively studied under high-pressure (HP) conditions [10,11]. As a result, first-order phase transitions, involving large volume changes, have been discovered at pressures below 10 GPa (for instance, the zircon-scheelite and zircon-monazite transitions in alkaline earth vanadates [10,11]). Many of these transitions lead to interesting phenomena such as a collapse of the electronic band gap [12]. In contrast, very little effort has been dedicated to study kagome staircase orthovanadates under HP. Indeed, only two works can be found in the literature [7,9]. One of them reports powder X-ray diffraction (XRD) data on Zn₃V₂O₈ up to 15 GPa [7]. No phase transition was detected and an anisotropic response to compression was determined. The second one reports the influence of pressure on the magnetic properties of Ni₃V₂O₈ up to 2 Gpa [9]. Therefore, despite the interesting physics involved, the HP behavior of M₃V₂O₈ orthovanadates is an underexplored research area.

Here, we report a study of the HP behavior of the structural properties of Ni₃V₂O₈. The information obtained from such studies can form a foundation for future studies on the influence of pressure in physical properties, including magnetic properties. We have performed synchrotron powder XRD experiments in Ni₃V₂O₈ up to 23 Gpa at ambient temperature, thereby obtaining information on the structural stability of compressibility of the compound. The rest of the paper is organized as follows. Section 2 is devoted to the description the experimental methods. In Section 3, the results are reported and discussed in comparison with Zn₃V₂O₈ and other isostructural M₃V₂O₈ vanadates. Concluding remarks are given in Section 4.

Figure 1. (a) Crystal structure of Ni₃V₂O₈. NiO₆ octahedra are shown in grey and VO₄ tetrahedra are in red. Small red circles are oxygen atoms. (b) Projection of the crystal structure showing VO₄ tetrahedra (in red) and Ni atoms (in gray) connected to make more evident the kagome staircase framework. Three unit cells are included in (b). The unit cell is shown in black solid lines.

2. Materials and Methods

Powder samples of Ni₃V₂O₈ were synthesized via a solid-state reaction starting from NiO (99.995% purity) and V₂O₅ (99.9% purity). The starting reagents were obtained from Alfa Aesar (Tewksbury, MA, United States). They were mixed meticulously and subsequently heated in an Al₂O₃ crucible in air at 800 °C for 16 h. The product was then ground and pressed into a pellet, to be afterward sintered at 900 °C for an additional 16 h. The obtained sample was finally ground manually in an agate mortar to obtain a micron size powder. In order to characterize it, we performed powder XRD measurements using a X’Pert Pro diffractometer from Panalytical (Almelo, The Netherlands) with Cu Kα₁ radiation (λ = 1.5406 Å). The measurements were performed in the angular range 10° < 2θ < 70°, by continuous scanning with a step size of 0.02° and total step time of 200 s.

Angle-dispersive X-ray diffraction experiments at room-temperature and high pressure were performed at beamline I15 of the Diamond Light Source using a membrane-type diamond-anvil cell (DAC) with diamond-culet sizes of 450 μm in diameter and monochromatic X-rays of λ = 0.42466 Å. The X-ray beam was focused down to 10 × 10 μm². A rocking (±10°) of the DAC was used to improve the
homogeneity of the Debye rings. A fine powder of Ni$_3$V$_2$O$_8$ was loaded in a 150 µm hole of a rhenium gasket pre-indented to a 40 µm thickness. One grain of Cu was loaded together with the sample and used as internal standard for pressure determination. For this purpose, we used the equation of state (EOS) determined by Dewaele et al. under hydrostatic conditions [13]. A 16:3:1 methanol–ethanol–water (MEW) mixture was used as a pressure-transmitting medium [14,15]. The powder XRD patterns were collected using a Pilatus 2M detector (DECTRIS, Baden, Switzerland) and transformed into one-dimensional patterns using the DIOPTAS suite [16]. The sample-to-detector distance was measured following standard procedure from the diffraction rings of LaB$_6$.

3. Results and Discussion

The results of the ambient-conditions XRD measurements are shown in Figure 2. All of the observed reflections can be accounted for by the orthorhombic crystal structure reported in the literature (space group $Cmca$, No. 64) [17], leading to small residuals (see Figure 2) and converging to small R-factors: $R_p = 2.39\%$ and $R_{WP} = 3.79\%$. The resulting unit-cell parameters were $a = 5.928(4)$ Å, $b = 11.384(6)$ Å, and $c = 8.241(5)$ Å, which agree to within 0.1% of literature values [17]. The obtained atomic positions are reported in Table 1, being also in good agreement with the literature [17].

Figures 3–5 show sequential integrated XRD patterns acquired up to 23 GPa on compression of Ni$_3$V$_2$O$_8$. In Figure 3, it can be seen that over the complete pressure range of the experiments, all the reflections can be assigned to the known orthorhombic structure of Ni$_3$V$_2$O$_8$ and to Cu (the pressure marker), which is supported by a profile matching analysis using the Le Bail method. Therefore, no phase transition is observed in Ni$_3$V$_2$O$_8$ up to 23 GPa. More details of the HP X-ray patterns can be seen in Figures 4 and 5. Figure 4 shows results for $P \leq 7$ GPa and Figure 5 shows results from 7.6 to 23 GPa. Beyond 20 GPa, we detected the presence of one extra reflection originating from the Re gasket, which appears because of the reduction in the size of the sample chamber. The data in Figures 3 and 4 show a change of relative peak intensities under increasing compression. This is related to the development of preferred crystallite orientation relative to the X-ray beam. Under compression, we also observe that the position of peaks indexed as 0$k$0 is less sensitive to pressure, and that they move less towards higher angles than the rest of the peaks. This can be observed in Figure 4 by comparing the pressure evolution of peaks identified with planes (131) and (040), since the (131) peak approaches the stationary (040) peak. As we will discuss below, this observation is rooted in the non-isotropic behavior of Ni$_3$V$_2$O$_8$. Another consequence of the anisotropic behavior is the gradual merging of peaks; for instance, those identified with planes (221) and (023). Their merging under compression can be seen in Figures 3, 4, and 5. In addition, beyond 7.6 GPa, we have observed a gradual broadening of the peaks (Figure 5), which is related to the gradual loss of quasi-hydrostaticity [15,18].

Figure 3. Integrated XRD patterns of Ni$_3$V$_2$O$_8$ from 0 to 23 GPa. Pressures are indicated on each pattern and the Bragg planes corresponding to the most intense reflections have been labeled. The experiments are shown with symbols. The refinements, assuming the ambient-pressure orthorhombic structure, are shown with black lines. The difference between the observed data and Le Bail refinement is shown in green. Ticks indicate the positions of Ni$_3$V$_2$O$_8$ peaks.
Through performing Le Bail refinements of the powder XRD patterns, we have obtained the pressure dependence of the unit-cell parameters. The XRD patterns at all pressures can be identified with the ambient-pressure orthorhombic structure of \( \text{Ni}_3\text{V}_2\text{O}_8 \); however, the XRD patterns measured at pressures higher than 15.1 GPa have been excluded from this analysis due to the partial overlap of the Cu peak used to determine pressure with a diffraction peak from the sample (see Figure 5), because this could lead to inaccuracies in the pressure determination larger than 0.2 GPa. The unit-cell parameters as a function of pressure are shown in Figure 6. This information is important for modeling the suppression of ferroelectricity by pressure in \( \text{Ni}_3\text{V}_2\text{O}_8 \) [9]. The response of the crystal structure to compression is clearly non-isotropic, with the \( b \) and \( a \) axes, respectively, having the smallest and largest compressibility. The anisotropic compressibility observed in \( \text{Ni}_3\text{V}_2\text{O}_8 \) is fully compatible with the

anisotropic thermal expansion of the same compound [9]. Both results can be rationalized based on the layered characteristic of the kagome staircase in the crystal structure and the relative compressibilities of the constituent polyhedra, as discussed below.

**Figure 5.** Integrated XRD patterns of Ni$_3$V$_2$O$_8$ measured from 7.6 to 23 GPa. Pressures are indicated on each pattern, and Bragg planes corresponding to the most intense reflections have been labeled. At the bottom and top, traces observed experimental data are shown with black symbols. The refinements are shown with black lines. The difference between the observed data and Le Bail refinement is shown in green. In the figure, it can be clearly seen the merging and broadening of peaks described in the text.

From the hydrostatic pressure range of our experiments ($P \leq 7.6$ GPa), we have determined the linear compressibilities at ambient pressure, $\kappa_x = -\frac{1}{V} \frac{\partial V}{\partial P}$, where $x$ represents the unit cell lengths $a$, $b$, or $c$. The linear compressibilities are summarized in Table 2, where it can be seen that they increase following the sequence $\kappa_b < \kappa_c < \kappa_a$. The $a$ and $c$-axes have larger compressibilities than the $b$-axis by approximate factors of 1.5 and 1.3, respectively. A similar behavior has previously been observed in Zn$_3$V$_2$O$_8$. 

![Figure 5](image-url)
(see Figure 1), the crystal structure of M3V2O8 compounds is composed of 2D kagome staircases of V 3d - O 2p hybridization [20], changes little under compression [10]. As we have already described (see Figure 1), the crystal structure of M3V2O8 compounds is composed of 2D kagome staircases of compressible MO6 octahedra, which therefore constitute compressible layers that lie perpendicular to the b-axis. In between these layers of NiO6 and ZnO6 octahedra, there are located the less compressible VO4 tetrahedra, which are arranged to form pillars between the kagome layers, reducing the compressibility along the b-axis. In fact, the in-plane effective bulk modulus [21] for kagome layers is 132 GPa, and the effective bulk modulus in the perpendicular direction is 186 GPa. Thus, the layered characteristic of the crystal structure of kagome-type vanadates provides a rational explanation to their anisotropic behavior under compression. The present results suggest that it is not unreasonable to speculate that anisotropic compressibility would be a fingerprint of the broad family of kagome-type compounds. Such anisotropic behavior is expected to affect super-exchange interactions between magnetic atoms, thereby modifying the temperature of different magnetic transitions. This would modify the Néel temperature as reported for Ni3V2O8 [9]. By extrapolating the result reported by Chaudhury et al. [9], it can be speculated that under compression the Néel temperature can be increased from 9.8 K at ambient pressure to a temperature close to 15 K at 20 GPa.

![Figure 6. Normalized unit-cell parameters of Ni3V2O8 as a function of pressure. Symbols are the results from Le Bail refinements. The lines describe unidirectional equations of state (EOSs) described in the text. Where not shown error bars are comparable to symbols’ size.](image_url)
vanadates using the bulk moduli summarized in Table 3. In Table 3, it can be seen that Ni\(_3\)V\(_2\)O\(_8\) is the most incompressible compound within M\(_3\)V\(_2\)O\(_8\) family of isomorphic vanadates. For the discussion, based on the fact that NiO\(_6\) units are more compressible than rigid VO\(_4\) units [10,19], we will assume Ni\(_3\)V\(_2\)O\(_8\) to be the most incompressible and use the bulk modulus for Ni\(_3\)V\(_2\)O\(_8\). We will now comment on the bulk modulus of Ni\(_3\)V\(_2\)O\(_8\) within the context of other M\(_3\)V\(_2\)O\(_8\) vanadates [25,26] using the bulk moduli summarized in Table 3. In Table 3, it can be seen that Ni\(_3\)V\(_2\)O\(_8\) is the most incompressible compound within M\(_3\)V\(_2\)O\(_8\) family of isomorphic vanadates. For the discussion, based on the fact that NiO\(_6\) units are more compressible than rigid VO\(_4\) units [10,19], we will assume $K_0$ is the ambient-pressure bulk modulus. $K_0'$ is the pressure derivative of the bulk modulus.

The unit-cell volume of Ni\(_3\)V\(_2\)O\(_8\) as a function of pressure is shown in Figure 7. The results show a change in compressibility is in fact related to the known hydrostatic limit for MEW [15]. Fitting a third-order Birch–Murnaghan EOS for $P \leq 7.6$ (15.1) GPa. As stated in the text, results deviate from the quasi-hydrostatic EOS for $P \leq 7.6$ GPa likely due to the influence of non-hydrostaticity. We will now comment on the bulk modulus of Ni\(_3\)V\(_2\)O\(_8\) within the context of other M\(_3\)V\(_2\)O\(_8\) vanadates [25,26] using the bulk moduli summarized in Table 3. In Table 3, it can be seen that Ni\(_3\)V\(_2\)O\(_8\) is the most incompressible compound within M\(_3\)V\(_2\)O\(_8\) family of isomorphic vanadates. For the discussion, based on the fact that NiO\(_6\) units are more compressible than rigid VO\(_4\) units [10,19], we will assume...
that the bulk modulus of Ni$_3$V$_2$O$_8$ is mainly determined by the average Ni-O distance ($d_{Ni-O}$) at ambient pressure and the formal charge of Ni ($Z_{Ni}$). Such an empirical approximation works very well for ternary oxides [27,28], whereby the estimated bulk modulus is given by $B_E = \frac{610 \cdot Z_{Ni}}{d_{Ni-O}^2}$. Using this approximation, a bulk modulus of 140 GPa is obtained for Ni$_3$V$_2$O$_8$, which agrees within errors with the experimental value obtained from the hydrostatic-pressure regime (139(3) GPa). This suggests that the bulk modulus obtained from density-functional theory (DFT) calculations (130.4–131.2 GPa, given in Table 3) has been underestimated by ~7% of the experimental value determined here. This fact is probably related to the overestimation of the ambient-pressure volume by DFT calculations [29], which is a typical feature of the general-gradient approximation used in previous computer simulations [25,26].

By using the same empirical approximation, we have estimated the bulk modulus for other M$_3$V$_2$O$_8$ vanadates, which are summarized in Table 3 for comparison with the literature. For example, in the case of Zn$_3$V$_2$O$_8$, the estimated bulk modulus is consistent with the fact that this compound has an experimentally determined bulk modulus smaller than that for Ni$_3$V$_2$O$_8$, which indicates that the approximation can be also applied to other kagome-type vanadates. In performing the empirical approximations summarized in Table 3, we found that DFT calculations have also underestimated the bulk modulus of Cu$_3$V$_2$O$_8$ and Mn$_3$V$_2$O$_8$. Using the empirical approximation, which works well for the studied vanadates, we can predict bulk moduli of 132 and 131 GPa for Mg$_3$V$_2$O$_8$ and Co$_3$V$_2$O$_8$, respectively, which have not yet been investigated under compression. The conclusions reported in this work may be also applicable to isomorphic arsenates [30], to (Ni,Mg)$_3$(VO)$_2$ solid solutions [31], and to hydrated kagome-structured vanadates, such as Cu$_3$V$_2$O$_7$(OH)$_2$·2H$_2$O volborthite [32]. For the particular case of Ni$_3$As$_2$O$_8$, a bulk modulus of 205 GPa is predicted from the empirical model used in this work.

### 4. Conclusions

Through synchrotron powder X-ray diffraction measurements, we have determined that at ambient temperature the orthorhombic kagome staircase crystal structure of Ni$_3$V$_2$O$_8$ is stable at least up to 23 GPa, the maximum pressure achieved in present experiments. We have also found that the response to compression is anisotropic. The compressibility of the $b$-axis is approximately 40% lower than the compressibility of the other axes. This special direction is perpendicular to the kagome layers, and the compression along the $b$-axis is the smallest due to the presence of incompressible VO$_4$ tetrahedral units, which interconnect the kagome staircases of NiO$_6$ octahedra. From the pressure dependence of the unit-cell volume we fitted a third-order Birch–Murnaghan equation of state, giving a bulk modulus of 139(3) GPa, which is the largest among isostructural M$_3$V$_2$O$_8$ vanadates. A systematic comparison of bulk moduli in isomorphic M$_3$V$_2$O$_8$ vanadates is made based on an empirical method for predicting bulk moduli in ternary oxides. The results are consistent with those determined from experimental data here for Ni$_3$V$_2$O$_8$ and previously for Zn$_3$V$_2$O$_8$ [7]. Therefore, we also present
predicted bulk moduli of $\text{M}_3\text{V}_2\text{O}_8$ compounds not studied yet under high pressure, $\text{Co}_3\text{V}_2\text{O}_8$ and $\text{Mg}_3\text{V}_2\text{O}_8$.
