Abstract: In this paper, a fault-tolerant control method is proposed for quadcopter unmanned aerial vehicles (UAV) to account for system uncertainties and actuator faults. A mathematical model of the quadcopter UAV is first introduced when faults occur in actuators. A normal adaptive sliding mode control (NASMC) approach is proposed as a baseline controller to handle the chattering problem and system uncertainties, which does not require information of the upper bound. To improve the performance of the NASMC scheme, radial basis function neural networks are combined with an adaptive scheme to make a quick compensation in presence of system uncertainties and actuator faults. The Lyapunov theory is applied to verify the stability of the proposed methods. The effectiveness of modified ASMC algorithm is compared with that of NASMC using numerical examples under different faulty conditions.

Keywords: fault diagnosis; quadcopter UAV; fault tolerant control; radial basic function; adaptive sliding mode control

1. Introduction

Quadcopter unmanned aerial vehicles (UAVs) are used in a wide range of applications and research, owing to their various benefits include agility, economical cost, small size, mechanical simplicity, and ability to operate in dangerous environments, which has led them to be more popular than other UAV systems. Therefore, they have been studied and tested in various technologies including target tracking [1,2], fault diagnosis, and fault tolerant control [3–5], and formation control [6,7].

In real applications, the translation movement of the quadcopter is controlled by an operator with the support of a remote-control system, whereas rotation movement is operated automatically via an onboard controller unit. To operate a quadcopter in the desired position the attitude controller plays an important role, because it allows the quadcopter to maintain the desired rotation and prevents crashing when the operator performs the desired translation movement [8]. One problem with the attitude control of quadcopter UAVs is the uncertainties and unknown disturbances that the quadcopter is subjected to during operation. This issue has been investigated previously based on various control methods, such as adaptive control [9], sliding mode control [10,11], and backstepping control [12,13]. If faults occur, control of the quadcopter becomes more challenging [14], which could result in a failure during the mission. Therefore, fault-tolerant control (FTC) is a key factor that needs be considered intensively in attitude-controller design. The topic of FTC has drawn attention in academic communities owning to enhanced safety and reliability demands. In general, there are three type of faults in FTC systems: Actuator, sensor, and process faults. Since the actuator is an important component that can connect control signals and specific movements to achieve a particular objective, actuator faults are addressed in this article. Passive FTC methods are used to accommodate this type of fault, which do not require fault detection and identification units as in active FTC methods [13].
Actuator faults are examined as uncertainties and they are treated using the passive FTC approach. Sliding mode control (SMC) is a passive FTC method for designing control systems dealing with model uncertainties and external disturbances. Studies by Kacimi et al. [13], Sharifi et al. [14], and Bouchoucha et al. [15] show some acceptable results using SMC approaches. SMC has the advantage of insensitivity to unknown disturbances and parametric uncertainties which makes it a promising method [16]. However, the bound of uncertainties needs to be designed in traditional SMCs. In several applications, the magnitude of the actuator fault cannot be known, and it is difficult to achieve the bound of uncertainty in advance. This motivates a new control method, which combines adaptive algorithms with SMC to enhance the tracking performance and robustness of the system without knowledge of the information of the uncertainty bound. Many existing studies have introduced the design of adaptive SMC [17–23], which integrates the adaptive law into the normal SMC to enhance the robustness of control performance. However, these studies have not investigated the actuator faults in the quadcopter model.

There are minor studies using adaptive SMC approaches to handle actuator faults. In references [24–26], the ASMC shows good results for the tracking performance with an actuator fault; however, these control approaches may not have sufficient robustness because the accurate model needs to be achieved in state space representation. Another complex method based on a fuzzy system is proposed in reference [27]. A fuzzy compensator is used to handle disturbances, actuator faults, and to avoid the high gain of adaption rate but this control law still requires the information of bound and it is challenging to find the fuzzy rule through the trial and error method. The active FTC based on adaptive SMC approach have been proposed in reference [28]. The results show good tracking performance in presence of actuator faults but the fault identification unit is required in this approach. Moreover, adaptive SMC based on the neural network have been investigated in reference [29–31]. These approaches show good responses without accurate model but actuator faults are not considered. The most recent work [10] proposed a simple adaptive SMC to handle uncertainties and disturbances. This method is simple to implement on quadcopter design and it shows good tracking performance. However, when a large fault occurs, this method cannot compensate quickly because the adaption rate is limited to ensure system stability. To solve this problem, radial basis function (RBF) neural networks are integrated into adaptive SMC [10] for fault identification and reconstruction through on-line approximation technique, which motivates our work in this paper.

In this article, we concentrate on developing an FTC method that can handle system uncertainties and actuator faults. The proposed method has some advantages such as using structure of RBF neural networks for fault identification and reconstruction, and using a simple adaptive scheme to avoid system uncertainties, and the chattering phenomenon. Moreover, this approach does not require the bound of uncertainty and fault detection unit which is different than the method in reference [32]. Finally, the control scheme in this paper is suitable for flight systems where the attitude control operates at a higher frequency than position control, which is different to the previous paper [33]. Unlike the paper [33], the radial basis function neural networks in this work are simpler than the fuzzy approach for fault reconstruction because the limitation of the fuzzy method is a trial and error technique for adjusting input variables. The contributions of this article can be summarized as follows. First, a mathematical model of the quadcopter is introduced with parametric uncertainties and disturbances. Second, a proportional-integral-derivative (PID) controller is used as position controller. Third, the RBF neural network scheme is proposed for fault identification and accommodation, whereas the adaptive scheme is used to handle the chattering phenomenon and uncertainties of system dynamics. Finally, the stability of the system is verified using the Lyapunov theory.
2. Quadcopter Modeling

2.1. Modeling of Quadcopter in Healthy Operation

The dynamics of the quadcopter UAV using Euler-Lagrange equations is described by Main and Daobo [20]. Figure 1 shows the torques and forces acting on the quadcopter. Assume that the dynamics of the quadcopter are considered in body-fixed coordinate B and earth-fixed coordinate E. The front and rear (1 and 3) motors rotate in a counter-clockwise direction; the other motors (2 and 4) rotate in a clockwise direction. The distance from the center to each rotor is denoted by $L$.

![Figure 1. Quadcopter configuration.](image)

The rotational and translation movement of the quadcopter can be described as follows [10,5]:

$$
\begin{align*}
\dot{\phi} &= \left( U_{\phi} + (I_y - I_z) \dot{\psi} - I_x \dot{\omega} - K_\phi \dot{\phi} \right) / I_x \\
\dot{\theta} &= \left( U_{\theta} + (I_x - I_z) \dot{\psi} - I_y \dot{\omega} - K_\theta \dot{\theta} \right) / I_y \\
\dot{\psi} &= \left( U_\psi + (I_z - I_x) \dot{\psi} - K_\psi \dot{\psi} \right) / I_z \\
\ddot{x} &= \left\{ U_x \left( \cos \theta \sin \psi + \sin \phi \sin \psi \right) - K_z \dot{x} \right\} / m \\
\ddot{y} &= \left\{ U_y \left( \cos \theta \sin \psi - \sin \phi \sin \psi \right) - K_z \dot{y} \right\} / m \\
\ddot{z} &= -g + \left\{ U_z \left( \cos \phi \cos \theta \right) - K_z \dot{z} \right\} / m
\end{align*}
$$

(1)

where $I_x, I_y, I_z$ represent the moments of inertia along the $x, y, z$ directions, respectively; $K_\phi, K_\theta, K_\psi, K_x, K_y, K_z$ are drag coefficients which depend on flight conditions; $I_r$ is the moment of inertia of each motor, and $\Omega = \Omega_x + \Omega_y + \Omega_z$; $m$ is the total mass; $\phi, \theta, and \psi$ denote the Euler angles; $x, y, and z$ represent the position of the quadcopter; and the four control inputs can be presented as

$$
\begin{align*}
U_x &= F_1 + F_2 + F_3 + F_4 \\
U_y &= (F_2 - F_3)L \\
U_\theta &= (F_3 - F_4)L \\
U_\psi &= \tau_1 - \tau_2 + \tau_3 - \tau_4
\end{align*}
$$

(2)

where $\tau_i = d \Omega_i^2$ and $F_i = b \Omega_i^2$ represents the torque and thrust force produced by the $i$th motor; $b, d$ are positive constants depending on the density of air, the radius of propeller, number of blades and geometry [11]; $\Omega_i$ represents the rotational speed of the $i$th motor. $U_x$ is the total thrust; $U_y, U_\theta, U_\psi$ are the torques in the $\phi, \theta, \psi$ directions, which correspond to the roll, pitch, and yaw Euler angles, respectively.
2.2. Modeling of Quadcopter in Faulty Operation

The dynamic model of the quadcopter in faulty operation can be presented by

\[
\begin{align*}
\dot{\varphi} &= \left( U_{\varphi} + (I_y - I_z) \dot{\theta} \dot{\psi} - J_z \dot{\Theta} \Omega - K_{\varphi} \dot{\varphi} \right) / I_x + \delta_{\varphi} \\
\dot{\theta} &= \left( U_{\theta} + (I_z - I_x) \dot{\varphi} \dot{\psi} - J_x \dot{\Phi} \Omega - K_{\theta} \dot{\theta} \right) / I_y + \delta_{\theta} \\
\dot{\psi} &= \left( U_{\psi} + (I_x - I_y) \dot{\varphi} \dot{\theta} - K_{\psi} \dot{\psi} \right) / I_z + \delta_{\psi} \\
\dot{x} &= \left\{ U_x (\cos \varphi \sin \theta \cos \psi + \sin \varphi \sin \psi) - K_x \dot{x} \right\} / m + \delta_x \\
\dot{y} &= \left\{ U_y (\cos \varphi \sin \theta \sin \psi - \sin \varphi \sin \psi) - K_y \dot{y} \right\} / m + \delta_y \\
\dot{z} &= -g + \left\{ U_z (\cos \varphi \cos \theta) - K_z \dot{z} \right\} / m + \delta_z
\end{align*}
\]

where \( U_{\varphi}, U_{\theta}, U_{\psi} \) and \( U_y \) are control inputs in faulty operation described by

\[
\begin{align*}
U_{\varphi} &= F_{\varphi} + F_{\varphi} + F_{\varphi} + F_{\varphi} \\
U_{\theta} &= L \left( F_{\varphi} - F_{\varphi} \right) \\
U_{\psi} &= L \left( F_{\varphi} - F_{\varphi} \right) \\
U_y &= d \left( F_{\varphi} - F_{\varphi} + F_{\varphi} - F_{\varphi} \right) / b
\end{align*}
\]

The fault model of the actuator can be presented by

\[
F_i = (1 - \gamma_i) F_i
\]

where \( 0 < \gamma_i < 1 \) (i = 1..4) indicates that the \( i \)th actuator loses partial effectiveness; the \( i \)th actuator is in healthy operation when \( \gamma_i = 0 \); the \( i \)th actuator loses effectiveness completely when \( \gamma_i = 1 \).

Substituting Equation (4) into Equation (3), we achieve

\[
\begin{align*}
\dot{\varphi} &= \left( U_{\varphi} + (I_y - I_z) \dot{\theta} \dot{\psi} - J_z \dot{\Theta} \Omega - K_{\varphi} \dot{\varphi} \right) / I_x + \delta_{\varphi} \\
\dot{\theta} &= \left( U_{\theta} + (I_z - I_x) \dot{\varphi} \dot{\psi} - J_x \dot{\Phi} \Omega - K_{\theta} \dot{\theta} \right) / I_y + \delta_{\theta} \\
\dot{\psi} &= \left( U_{\psi} + (I_x - I_y) \dot{\varphi} \dot{\theta} - K_{\psi} \dot{\psi} \right) / I_z + \delta_{\psi} \\
\dot{x} &= \left\{ U_x (\cos \varphi \sin \theta \cos \psi + \sin \varphi \sin \psi) - K_x \dot{x} \right\} / m + \delta_x \\
\dot{y} &= \left\{ U_y (\cos \varphi \sin \theta \sin \psi - \sin \varphi \sin \psi) - K_y \dot{y} \right\} / m + \delta_y \\
\dot{z} &= -g + \left\{ U_z (\cos \varphi \cos \theta) - K_z \dot{z} \right\} / m + \delta_z
\end{align*}
\]

where the unknown terms are presented by

\[
\begin{align*}
\delta_{\varphi} &= -L (\gamma_1 F_x - \gamma_2 F_z) / I_x \\
\delta_{\theta} &= -L (\gamma_2 F_x - \gamma_3 F_z) / I_y \\
\delta_{\psi} &= -d (\gamma_3 F_x - \gamma_4 F_z + \gamma_3 F_x - \gamma_4 F_z) / bI_x \\
\delta_x &= -(\cos \varphi \sin \theta \cos \psi + \sin \varphi \sin \psi) (\gamma_1 F_x + \gamma_2 F_z + \gamma_3 F_x + \gamma_4 F_z) / m \\
\delta_y &= -(\cos \varphi \sin \theta \sin \psi - \sin \varphi \sin \psi) (\gamma_1 F_x + \gamma_2 F_z + \gamma_3 F_x + \gamma_4 F_z) / m \\
\delta_z &= -\cos \varphi \cos \theta (\gamma_1 F_x + \gamma_2 F_z + \gamma_3 F_x + \gamma_4 F_z) / m
\end{align*}
\]

3. Controller Design

The control strategy of the quadcopter is presented in Figure 2. The altitude of the quadcopter is controlled by the total thrust \( (U_z) \). The desired angles of roll \( (\varphi_d) \) and pitch \( (\theta_d) \) are used for the rotational controller, which is achieved through the position controller. The desired yaw \( (\psi_d) \) is used to control the heading through the yaw controller (heading controller). The actual positions \( X, Y, \) and \( Z \) are achieved from the GPS unit, which is converted from the latitude and longitude signals.
The actual angles $\phi, \theta$, and $\psi$ are measured from the inertial measurement unit. The control inputs $U_\phi, U_\theta$, and $U_\psi$ are used to control the rotation movement of the quadcopter.

Figure 2. Control scheme of the quadcopter.

### 3.1. Fault Tolerant Control for Attitude System Using Normal Adaptive Sliding Mode Approach

Define the state vector $x = \begin{bmatrix} \phi & \dot{\phi} & \theta & \dot{\theta} & \psi & \dot{\psi} \end{bmatrix}^T = \begin{bmatrix} x_1 & x_2 & x_3 & x_4 & x_5 & x_6 \end{bmatrix}^T$ and control inputs $U = \begin{bmatrix} U_\phi & U_\theta & U_\psi \end{bmatrix}^T = \begin{bmatrix} u_1 & u_2 & u_3 \end{bmatrix}$. Then, the rotational movement equations of the quadcopter have the following form:

#### Roll control system

$\begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= f_1(x) + h_1 u_1(t) + d_1(x,t) + \xi_1
\end{align*}$

where $f_1(x) = \delta_\phi$, $h_1 = 1/I_x$, $d_1(x,t) = (I_y - I_z)/(I_x)(x_5 x_6) - J_x \dot{x}_4 \Omega$; $\xi_1 = -K_u x_2$ is the system uncertainty.

#### Pitch control system

$\begin{align*}
\dot{x}_3 &= x_4 \\
\dot{x}_4 &= f_2(x) + h_2 u_2(t) + d_2(x,t) + \xi_2
\end{align*}$

where $f_2(x) = \delta_\theta$, $h_2 = 1/I_y$, $d_2(x,t) = (I_z - I_x)/(I_y)(x_3 x_5) - J_y \dot{x}_3 \Omega$; $\xi_2 = -K_u x_4$ is the system uncertainty.

#### Yaw control system

$\begin{align*}
\dot{x}_5 &= x_6 \\
\dot{x}_6 &= f_3(x) + h_3 u_3(t) + d_3(x,t) + \xi_3
\end{align*}$

where $f_3(x) = \delta_\psi$, $h_3 = 1/I_z$, $d_3(x,t) = (I_x - I_y)/(I_z)(x_3 x_4)$; $\xi_3 = -K_u x_5$ is the system uncertainty.

Based on these rotational movement equations, each subsystem can be derived in the following form:

$\begin{align*}
\dot{x}_{2i-1} &= x_{2i} \\
\dot{x}_{2i} &= f_i(x) + h_i u_i(t) + d_i(x,t) + \xi_i
\end{align*}$

Let us define the desired attitude $x_i^d$. The control objective is to find the control law $u_i$ such that the quadcopter can track the desired attitude $x_i^d$ i.e., $x_{2i-1}(t) \to x_i^d$ as $t \to \infty$, $i = 1, 2, 3$. 

Define the control error:

\[ e_i = x_{2i-1} - x_i^d \]  

(12)

The sliding surface equation can be expressed as

\[ s_i = \dot{e}_i + c_i e_i \]  

(13)

where \( c_i \) is the positive gain.

The derivative of the sliding surface can be described as

\[ \dot{s}_i = \dot{\dot{e}}_i + c_i \dot{e}_i \]  

(14)

From Equations (12) and (14), \( \dot{s}_i \) can be described as

\[ \dot{s}_i = f_i(x) + h_i u_i(t) + d_i(x, t) + \xi_i - \hat{x}_i^d + c_i \dot{e}_i \]  

(15)

With the sliding surface in Equation (14), the fault tolerant control law can be expressed as

\[ u_i = (-d_i(x, t) - c_i \dot{e}_i + \hat{x}_i^d - \beta s_i - \hat{\Gamma}_i \text{sign}(s_i)) / h_i \]  

(16)

and updated by [10]

\[ \hat{\Gamma}_i = \alpha_{i2} |s_i| \]  

(17)

where \( \beta_i \) and \( \alpha_{i2} \) are positive numbers, and \( \text{sign}(.) \) denotes the sign function.

**Theorem 1.** If the sliding surface and control law are designed as Equations (14) and (16), then the nonlinear system Equation (11) is stable and the control errors are forced to zero.

**Proof.** Choose the Lyapunov function as follows

\[ V = \frac{1}{2} \dot{s}_i^2 + \frac{1}{2 \alpha_{i2}} \hat{\Gamma}_i^2 \]  

(18)

where \( \hat{\Gamma}_i = \Gamma_i - \hat{\Gamma}_i \); \( \hat{\Gamma}_i \) is the estimate of \( \Gamma_i \); \( \hat{\Gamma}_i = 0 \).

Take the first derivative of the Lyapunov function

\[ \dot{V} = s_i \dot{s}_i - \frac{\hat{\Gamma}_i \dot{\hat{\Gamma}}_i}{\alpha_{i2}} \]  

(19)

Substituting Equations (16) and (17) into Equation (19), we obtain

\[ \dot{V} = f_i(x) s_i + \xi_i \dot{s}_i - \beta s_i^2 - \Gamma_i |s_i| \leq -\beta s_i^2 - (\Gamma_i - [f_i(x) + \dot{\xi}_i]) |s_i| \]  

(20)

**Assumption 1.** The uncertainty \( \xi_t \) and the resultant of actuator faults \( f_i(x) \) are supposed to be bounded by \( |\xi_t| \leq \xi_t^d \) and \( |f_i(x)| \leq f_i^d \), where \( \xi_t^d \) and \( f_i^d \) are unknown positive constants. There exists the unknown parameter \( \Gamma_i > 0 \) such that \( |f_i(x) + \xi_i| \leq f_i^d + \dot{\xi}_i^d = \Gamma_i \).

From Assumption 1, it is shown that \( \dot{V} \leq 0 \). Assuming that \( s_t = 0 \), from Equation (14), we can obtain

\[ \lim_{t \to \infty} s_i = \lim_{t \to \infty} (\dot{\xi}_i + c_i e_i) = \lim_{t \to \infty} \left( \dot{x}_{2i-1} - \hat{x}_i^d \right) + c_i (x_{2i-1} - x_i^d) \]  

(21)

Because \( c_i \) is a positive number, Equation (14) can be expressed as

\[ \lim_{t \to \infty} (\dot{x}_{2i-1} - \hat{x}_i^d) = 0, \lim_{t \to \infty} (x_{2i-1} - x_i^d) = 0 \]  

(22)
Remark 1. Equation (22) shows that the NASMC designed as Equation (14) guarantees Lyapunov stability of system Equation (12). If $s_i \to 0$, then the control errors are forced to zero, which ensures the stability of the closed-loop system.

Remark 2. To avoid the chattering phenomenon due to sign function in control law Equation (16), a saturation function is introduced as

$$\text{sat}(s_i) = \begin{cases} s_i & \text{if} \ |s_i| \leq 1 \\ \text{sign}(s_i) & \text{if} \ |s_i| > 1 \end{cases} \quad \text{if} \quad i = 1, 2, 3 \quad \text{(23)}$$

Remark 3. In this method, only one parameter is designed to handle both system uncertainties and actuator faults. In Section 3.2, an RBF network is combined with adaptive law to handle system uncertainties and the actuator fault separately to ensure a quicker response during actuator faults.

3.2. Fault Tolerant Control for Attitude System Using Modified Adaptive Sliding Mode Approach

In this section, an RBF neural network is used to approximate function $f(x)$ to handle the actuator fault while the adaptive law is used to handle chattering and system uncertainties. The approximation method using the RBF network is presented in reference [34] as follows:

$$V_i = \exp \left( \frac{|x - c_i|^2}{2b_i^2} \right),$$

$$f_i(x) = W_i^T V_i(x) + \varepsilon_i,$$ \quad \text{(25)}

where $x = [e_i \ \dot{e}_i]$ is the input of the RBF neural network; $k$ the number of hidden nodes, $V_i$ is the output of Gaussian function, $W_i^T$ is the approximation weight, $\varepsilon_i$ is the approximation error assumed to be bounded by $|\varepsilon_i| \leq \varepsilon_i^*$, in which $\varepsilon_i^* > 0$ is a small positive constant.

The structure of the RBF network is shown in Figure 3. It consists of three layers: One input layer, one hidden layer, and one output layer. The inputs of the network are $e_i$ and $\dot{e}_i$.

Assumption 2. There exists an unknown parameter $\Gamma_i > 0$ such that $|e_i + \dot{e}_i| \leq \Gamma_i$

\[\text{Figure 3. Structure of radial basis function (RBF) neural network.}\]

Theorem 2. Consider the actuator fault in the system Equation (6) and the sliding surface in Equation (13). Suppose that the modified adaptive sliding mode control (MASMC) scheme for fault tolerant control is proposed as

$$u_i = h_i(-d_i(x,t) - c_i \dot{e}_i + \dot{\hat{\chi}} - \hat{W}_i^T V_i(x) - \hat{\Gamma}_i \text{sign}(s_i) - \beta \dot{s})$$ \quad \text{(26)}$$

and updated by

$$\dot{\hat{W}}_i = \alpha_i s_i V_i$$ \quad \text{(27)}$$
\[ \dot{\hat{\alpha}} = \alpha_2 |\hat{\alpha}| \]  

(28)

where \( \alpha_i, \alpha_j \) are positive gains. Then, it ensures that the stability of the closed-loop system and the control errors are forced to zero.

**Proof.** Lyapunov function candidate \( V \) is chosen as follows

\[ V = \frac{1}{2} \hat{\alpha}_i^2 + \frac{1}{2} \hat{\alpha}_j^2 + \frac{1}{2} \alpha_i \hat{\alpha}_i^2 + \frac{1}{2} \alpha_j \hat{\alpha}_j^2 \]  

(29)

where \( \hat{\alpha}_i = \alpha_i - \hat{\alpha}_i \) and \( \hat{\alpha}_j = \alpha_j - \hat{\alpha}_j \) are the estimates of \( \alpha_i \) and \( \alpha_j \), respectively.

Taking the first derivative of Lyapunov function candidate Equation (29), we obtain

\[ \dot{V} = s_i \hat{\alpha}_i - \frac{\hat{\alpha}_i^2}{\alpha_i} - \frac{\hat{\alpha}_j^2}{\alpha_j} = s_i (f(x) - W_i^T \dot{V}_j(x)) - s_i \hat{\alpha}_i^2 \]  

(30)

From Assumption 2, it shows that \( \lim_{t \to \infty} \alpha_i = \lim_{t \to \infty} (\dot{x}_i + c_i x_i) = \lim_{t \to \infty} (\dot{x}_i - c_i x_i) = 0 \). Because \( c_i \) is a positive number, we obtain

\[ \lim_{t \to \infty} (\dot{x}_i - c_i x_i) = 0, \lim_{t \to \infty} (x_i - c_i x_i) = 0 \]  

(31)

3.3. Position Control

A PID controller is applied to control the translational movements of the quadcopter as follows

\[ \ddot{X} = \ddot{X}_d + K_{p_x}(X - X_d) + K_{i_x}\int(X - X_d)dt \]  
\[ \ddot{Y} = \ddot{Y}_d + K_{p_y}(Y - Y_d) + K_{i_y}\int(Y - Y_d)dt \]  
\[ \ddot{Z} = \ddot{Z}_d + K_{p_z}(Z - Z_d) + K_{i_z}\int(Z - Z_d)dt \]  

(32)

where \( X_d, Y_d, \) and \( Z_d \) are the desired positions in the \( x, y, \) and \( z \) directions, respectively; \( X, Y, \) and \( Z \) are actual values; and \( K_{p_x}, K_{i_x}, K_{d_x}, K_{p_y}, K_{i_y}, K_{d_y}, K_{p_z}, K_{i_z}, K_{d_z}, K_{d}, \) and \( K_{d} \) are the controller gains.

Assume that the vehicle does not pass through singularities \( (\phi \neq \pi / 2 + k\pi, \theta \neq \pi / 2 + k\pi, k \in Z, U_x \neq 0) \). From translational movement Equation (1), we obtain the desired roll, pitch, and total thrust:

\[ U_z = -m\sqrt{\ddot{X}^2 + \ddot{Y}^2 + (\ddot{Z} - g)^2} \]  
\[ \dot{q}_d = \sin^{-1}\left( \frac{m\ddot{X}}{U_z} \sin(\psi) - \frac{m\ddot{Y}}{U_z} \cos(\psi) \right) \]  
\[ \theta_d = \cos^{-1}\left( \frac{m\ddot{Z} - mg}{U_z \cos(\phi)} \right) \]  

(33)

4. Simulation and Evaluation

In this section, to show the effectiveness of the proposed method, the quadcopter parameter in reference [10] is used for the simulation. The motion of the quadcopter is examined to track the
desired roll angle $\varphi_d$ with an actuator fault. The quadcopter is assumed to hover in position-hold mode. A filter is applied to generate the desired roll angles as follows [26]:

$$\ddot{\varphi}_d + 3\dot{\varphi}_d + 4\varphi_d = 4\varphi_y$$  \hspace{1cm} (34)

where $\varphi_y$ starts at 0° and increases to 5° at 5 s, and decrease to 0° at 10 s; then, it changes from 0° to −5° at 15 s, and increases to 0° at 20 s, finally, remains at 0° for the remaining time. Four different actuator faults are presented. The first case considers the 10% loss of control effectiveness (LoCE) in actuator 2 at 14s. In the second situation, the 50% LoCE in actuator 2 at 14 s and 20% uncertainty of inertia are examined. In the third case, the quadcopter is commanded to track the desired trajectory with 50% LoCE in both actuator 2 and 3 at 50 s and 70 s. In the final case, the quadcopter is commanded to track the desired trajectory with 50% LoCE in both actuator 1 and 3 at 50 s and 70 s.

For NASMC, parameters were selected as $c_j = 5$, $\beta_i = 50$ and $\alpha_{i2} = 150$. For comparison, the same parameters of $c_r, \beta_r, \alpha_{r2}$ were chosen in the proposed MASMC, and the remaining parameter $\alpha_{i1}$ was selected as 50. In position controller, $K_{px} = 6, K_{py} = 6, K_{pz} = 6, K_{dx} = 2, K_{dy} = 2, K_{dz} = 2, K_{v_r} = 1, K_{v_y} = 1, K_{v_z} = 1$ were chosen.

4.1. Case 1: 10% LoCE in Actuator 2

Figure 4 compares the tracking performance of the roll angle and error between the NASMC and MASMC methods, with 10% LoCE in actuator 2. From the initial time to 14 s, both methods can make a good tracking in roll angle and error with the same control input value shown in Figure 5a. In this stage, the control input is increased abruptly to change the roll angle from 0° to 5° at 5 s, and then it is decreased to change the roll angle from 5° to 0° at 10 s. After a small magnitude of fault is injected into actuator 2 at 14 s, the MASMC compensates quickly to track the desired roll angle. Furthermore, the MASMC demonstrates a quicker tracking error than the ASMC owning to it greater control effort when a fault occurs. From 15 s to 30 s, there is a similar trend in control effort for both NASMC and MASMC, which decreases the control effort at 15 s in order to change the roll angle from 0° to −5°, and then increases the control effort at 20 s to change roll angle from −5° to 0°. It should be noted that after fault occurs the MASMC can converge quickly to zero in tracking error. In all figures, $\varphi_d$, $\varphi_r$, and $\varphi_y$ represent the desired roll angle, actual roll angle using MASMC, and the actual roll angle using NASMC, respectively. $e_\psi$ and $e_{\varphi_r}$ represent the errors in roll angle using MASMC and NASMC. $U_{\psi}$ and $U_{\varphi_r}$ are the moments of roll determined from MASMC and NASMC through Equation (2).

Figure 5. Comparison of Control torque between NASMC and MASMC: (a) 10% LoCE in actuator 2; (b) 50% LoCE in actuator 2.

4.2. Case 2: 50% LoCE in Actuator 2 and 20% Uncertainties of the Inertia

To demonstrate the effectiveness of MASMC, a large fault is injected into actuator 2 with 50% LoCE at 14 s and 20% uncertainties of inertia is examined in the model of a quadcopter. Similar to case 1, from the initial time to 14 s, Figure 5b and Figure 6 show that both methods can use the same control torque value and make a good tracking in roll angle and error. When actuator fault is increased to 50% LoCE at 14 s, the NASMC shows an oscillation response at the initial stage and a low compensation to track the desired roll angle. In contrast, MASMC presents a very good tracking performance although there is a small overshoot at the initial stage after fault occurs. MASMC uses more control effort than ASMC when a fault occurs, and after 15 s there is a similar control effort for both NASMC and MASMC. It should be noted that after 15 s, there is a slow response in tracking performance of NASMC compared with MASMC shown in Figure 6.

Figure 6. Comparison of tracking performance between NASMC and MASMC with 50% LoCE in actuator 2: (a) Roll angle; (b) tracking error.

In both cases, by integrating the RBF neural networks into the NASMC approach the tracking error in roll angle can converge quickly to zero after fault occurs. The MASMC in both cases can detect and accommodate faults automatically through on-line approximation without using the fault detection unit.
4.3. Case 3: Multiple Faults Occurring in Actuator 2 and 3

This section shows the performance of MASMC in the presence of multiple faults occurring in actuator 2 and 3. Figure 7 presents the tracking performance in three positions \((X, Y, Z)\) while Figures 8, 9, and 10 show the corresponding Euler angles \((\phi, \theta, \psi)\), sliding surface, and control inputs \((U_r, U_\theta, U_\psi)\). According to these figures, when faults occur in actuator 2 and 3 at 50 s and 70 s, respectively, the altitude is decreased at 50 s and 70 s due to loss of thrust force, and then it can compensate steadily through the PID controller. The actual trajectories in \(X, Y\) directions can converge quickly to the desired ones in the presence of faults. It should be noted that when the attitude controller can respond quickly to handle actuator faults through the fault tolerant controller, the responses of \(x, y\) directions will be improved.

Figure 9. Sliding surface: (a) Pitch angle; (b) roll angle; (c) yaw angle.
4.4. Case 4: Multiple Faults Occurring in 1 and 3

In this situation, 50% LoCE in actuator 1 and 3 is considered at 50 s, and 70 s, respectively. Figure 11 presents the tracking performance in three positions (X, Y, Z) while Figures 12, 13, and 14 show the corresponding Euler angles (φ, θ, ψ), sliding surface, and control inputs (Uφ, Uθ, Uψ, Uψ). According these Figures, when faults occur at 50 s and 70 s, the altitude is decreased at 50 s and 70 s due to loss of thrust force and then altitude can compensate steadily through the PID controller. The actual trajectories in X, Y directions can converge quickly to the desired ones in the presence of faults. It should be noted that although faults occur on the same axis of the quadcopter, the system still maintains the stability.

Figure 11. Tracking performance in three positions: (a) x-direction; (b) y-direction; (c) z-direction; (d) zoomed x-direction at 50 s; (e) zoomed x-direction at 70 s.
Remark 4. In all cases, the computational complexity in MASMC depend on hidden nodes in RBF neural networks. Therefore, the user can choose the suitable hidden nodes for controller design. For simplicity, we used seven hidden nodes in MASMC.

5. Conclusion

In this paper, a model of a quadcopter was examined in the presence of actuator faults and uncertainties. An NASMC was designed as a baseline controller to handle actuator faults, uncertainties, and chattering phenomenon. An MASMC which integrates RBF neural network into NASMC was investigated to make a quick compensation when large faults occur. The proposed MASMC does not require a fault identification unit and bound of uncertainty. To verify the suggested
method, the model of the quadcopter along with the proposed controllers were simulated in different cases. The results show that the MASMCC can make a quick compensation and a good trajectory tracking compared with NASMC. However, the limitation of this work is that the proposed MASMCC does not consider the complete loss of the actuator fault and does not verify through experiment. The future research should concentrate on experimental results of the proposed method, and should examine complete loss effectiveness in actuator using the fault identification technique.
