Abstract: The primary objective of this manuscript is to obtain the approximate analytical solution of Camassa–Holm (CH), modified Camassa–Holm (mCH), and Degasperis–Procesi (DP) equations with time-fractional derivatives labeled in the Caputo sense with the help of an iterative approach called fractional reduced differential transform method (FRDTM). The main benefits of using this technique are that linearization is not required for this method and therefore it reduces complex numerical computations significantly compared to the other existing methods such as the perturbation technique, differential transform method (DTM), and Adomian decomposition method (ADM). Small size computations over other techniques are the main advantages of the proposed method. Obtained results are compared with the solutions carried out by other technique which demonstrates that the proposed method is easy to implement and takes small size computation compared to other numerical techniques while dealing with complex physical problems of fractional order arising in science and engineering.

Keywords: shallow water wave; Caputo derivative; Camassa–Holm equation; differential transform method

1. Introduction

Nonlinear phenomena are of significant importance in natural sciences and engineering. Most of our real-life problems are modeled through the use of nonlinear phenomena. In the present years, fractional calculus has become widespread because of its applications in mathematical biology, electrochemistry, and physics [1–8]. For example, the earthquake model [9] and traffic model [10] with fractional derivatives have been demonstrated. However, sometimes, it is challenging to find the exact and numerical solutions of these models. During the last few decades, several analytical and numerical approaches have been established for the solution of such types of models such as homotopy perturbation method (HPM) [10,11], homotopy perturbation transform method [12,13], homotopy analysis method (HAM) [14,15], Adomian decomposition method (ADM) [16,17], sine-cosine method [18] and transform method [19]. Recently, multi-dimensional diffusion equation of fractional order has been solved by Kumar et al. [20] by modified HPM (m-HPM). In this approach, parameter p has been presented to extend the solution in series form, whereas the nonlinear terms can be extended by using He’s polynomial [21]. It has been observed that the computation of He’s polynomial is complicated, and the main disadvantage of this approach is its complexity in that regard and enormous calculations.

Among all the listed method, FRDTM plays a vital role because it takes small size computation, easy to implement as compared to other techniques. It was first introduced and developed by Keskin and Oturanc [22]. It is a beneficial and powerful semi-analytical approach. By implementation of the FRDTM,
many physical nonlinear problems can be solved easily. In this article, the nonlinear time-fractional Camassa–Holm (CH) equation is taken as [23,24]

\[
\begin{align*}
\frac{\partial^{\alpha} \psi}{\partial t^{\alpha}} + 2c \frac{\partial \psi}{\partial x} \frac{\partial \psi}{\partial x} - 3 \psi \frac{\partial \psi}{\partial x} - 2 \psi \frac{\partial \psi}{\partial x} + \psi \frac{\partial \psi}{\partial x} = 0,
\end{align*}
\]

for \( t > 0, x \in \mathbb{R}, 0 < \alpha \leq 1, \) (1)

with initial condition (IC)

\[
\psi(x, 0) = g(x),
\]

(1a)

The modified Camassa–Holm (mCH) and Degasperis–Procesi (DP) equations are derived from modified \( b \)-equation [25] which is

\[
\frac{\partial \psi}{\partial t} - \frac{\partial^{3} \psi}{\partial x^{2} \partial t} + (b + 1) \psi^{2} \frac{\partial \psi}{\partial x} = b \frac{\partial \psi}{\partial x} \frac{\partial^{2} \psi}{\partial x^{2}} + \psi \frac{\partial^{3} \psi}{\partial x^{3}}
\]

(1b)

where \( b \) is a positive integer.

The time-fractional mCH and time-fractional DP are derived from fractional modified \( b \)-equation which may be written as

\[
\begin{align*}
\frac{\partial^{\alpha} \psi}{\partial t^{\alpha}} - \frac{\partial^{3} \psi}{\partial x^{2} \partial t} + (b + 1) \psi^{2} \frac{\partial \psi}{\partial x} &= b \frac{\partial \psi}{\partial x} \frac{\partial^{2} \psi}{\partial x^{2}} + \psi \frac{\partial^{3} \psi}{\partial x^{3}}
\end{align*}
\]

(1c)

By substituting \( b = 2, b = 3 \) into Equation (1c), we obtain the time-fractional mCH equation and time-fractional DP equation, respectively. So, the nonlinear time-fractional mCH equation is written as [11,24,25]

\[
\begin{align*}
\frac{\partial^{\alpha} \psi}{\partial t^{\alpha}} - \frac{\partial^{3} \psi}{\partial x^{2} \partial t} + 3 \psi^{2} \frac{\partial \psi}{\partial x} &= 2 \frac{\partial \psi}{\partial x} \frac{\partial^{2} \psi}{\partial x^{2}} + \psi \frac{\partial^{3} \psi}{\partial x^{3}}, \text{ for } t > 0, x \in \mathbb{R}, 0 < \alpha \leq 1
\end{align*}
\]

(2)

with IC

\[
\psi(x, 0) = p(x),
\]

(2a)

and the nonlinear time-fractional DP equation is given as [11,24,25]

\[
\begin{align*}
\frac{\partial^{\alpha} \psi}{\partial t^{\alpha}} - \frac{\partial^{3} \psi}{\partial x^{2} \partial t} + 4 \psi^{2} \frac{\partial \psi}{\partial x} &= 3 \frac{\partial \psi}{\partial x} \frac{\partial^{2} \psi}{\partial x^{2}} + \psi \frac{\partial^{3} \psi}{\partial x^{3}}, \text{ for } t > 0, x \in \mathbb{R}, 0 < \alpha \leq 1
\end{align*}
\]

(3)

with IC

\[
\psi(x, 0) = f(x),
\]

(3a)

These three models are the unidirectional shallow water waves propagation over a flat bottom. Equation (1) is a shallow water wave equation and was initially determined as an estimation to the incompressible Euler equation and observed to be integrable with a Lax pair [26]. Equation (3) is the shallow-water dynamics model and found to be completely integrable. All the equations possess not only the peakon solutions but also the multi-peakon solutions [26]. Recently, Degasperis and Gaeta [27] have been examined the behavior of the DP equation with the help of the bifurcation theory of dynamical system. To the best of authors’ knowledge, for the first time, the fractional-order three relevant wave equations have been studied by the present authors analytically using FRDTM.

This article is prepared as follows: In Section 2, the essential features of fractional calculus related to the titled problem are included. Fundamental theories of FRDTM are described in Section 3. In Sections 4–6, implementations of FRDTM on CH, mCH, and DP equation are incorporated respectively. Numerical results and discussion are discussed in Section 7. Lastly, a conclusion is given in Section 8.
2. Preliminaries

**Definition 1.** The operator \( D_x^\alpha \) of \( u(x) \) in Riemann-Liouville (R-L) sense is written as

\[
D^\alpha u(x) = \begin{cases} 
\frac{d^m}{dt^m} u(x), & \alpha = m \\
\frac{\Gamma(m-\alpha)}{\Gamma(m)} \frac{d^m}{dt^m} \int_0^x \frac{u(t)}{(x-t)^{\alpha+m-1}} dt, & m-1 < \alpha < m
\end{cases}
\]

where \( m \in \mathbb{Z}^+, \alpha \in \mathbb{R}^+ \).

**Definition 2.** The operator \( J_x^\alpha \) of \( u(x) \) in R-L sense is described as

\[
J^\alpha u(x) = \frac{1}{\Gamma(\alpha)} \int_0^x (x-t)^{\alpha-1} u(t) dt, \quad t > 0, \quad \alpha > 0.
\]

Following Podlubny [1] we may have

\[
J^\alpha t^n = \frac{\Gamma(n+1)}{\Gamma(n+\alpha+1)} t^{\alpha+n}.
\]

\[
D^\alpha t^n = \frac{\Gamma(n+1)}{\Gamma(n-\alpha+1)} t^{n-\alpha}.
\]

**Definition 3.** The operator \( \mathcal{D}_x^\alpha \) of \( u(x) \) in the Caputo sense is defined as

\[
\mathcal{D}^\alpha u(x) = \begin{cases} 
\frac{1}{\Gamma(m-\alpha)} \int_0^x \frac{u^m(t)}{(x-t)^{\alpha+m-1}} dt, & m-1 < \alpha < m \\
\frac{d^m}{dx^m} u(x), & \alpha = m
\end{cases}
\]

**Definition 4.**

(a) \( \mathcal{D}_t^\alpha \mathcal{I}_t^\beta f(t) = f(t) \),

(b) \( \mathcal{I}_t^\beta \mathcal{D}_t^\alpha f(t) = f(t) - \sum_{k=0}^{m} f^{(k)}(0^+) \frac{t^k}{k!}, \text{ for } t > 0 \text{ and } m-1 < \alpha \leq m \).

3. FRDTM

**Definition 5.** Fractional reduced differential transform of an analytic and continuously differentiable function \( u(x,t) \) is defined by

\[
U_k(x) = \frac{1}{\Gamma(\alpha k + 1)} \mathcal{D}_t^{\alpha k} u(x,t) \bigg|_{t=t_0} \text{ for } k = 0, 1, 2, \ldots
\]

Taking the inverse transform of \( U_k(x) \) is defined as

\[
u(x,t) = \sum_{k=0}^{\infty} U_k(x)(t-t_0)^{\alpha k}
\]

From Equations (11) and (12), we have

\[
u(x,t) = \sum_{k=0}^{\infty} \frac{1}{\Gamma(\alpha k + 1)} \mathcal{D}_t^{\alpha k} u(x,t) \bigg|_{t=t_0} (t-t_0)^{\alpha k}
\]
In particular, at $t_0 = 0$, we get

$$ u(x, t) = \sum_{k=0}^{\infty} U_k(x) t^k = \sum_{k=0}^{\infty} \left( \frac{1}{\Gamma(ak+1)} \right) [D_t^{ak} u(x, t)]_{t=0}^k $$

(14)

As such Table 1 incorporates fractional reduced differential transform of few standard functions.

**Table 1.** The major operation of fractional reduced differential transform method (FRDTM) [22].

</tbody>
</table>

In order to explain the concept of FRDTM, let us consider the following equation in the operator form as

$$ L\psi(x, t) + R\psi(x, t) + N\psi(x, t) = h(x, t), $$

(15)

with IC

$$ \psi(x, 0) = g(x), $$

(16)

where $L = \frac{d^a}{dt^a}, R, N$ are linear, nonlinear operators and $h(x, t)$ is an inhomogeneous source term.

Using Table 1 and Equation (11), Equation (15) reduces to

$$ \frac{\Gamma(1+ak+a)}{\Gamma(1+ak)} \psi_{k+1}(x) = H_k(x) - R\psi_k(x) - N\psi_k(x), \text{ for } k = 0, 1, 2 \ldots $$

(17)

where $\psi_k(x)$ and $H_k(x)$ are the transformed forms of $\psi(x, t)$ and $h(x, t)$, respectively.

Applying FRDTM on IC, we obtain

$$ \psi_0(x) = g(x), $$

(18)

Using Equations (17) and (18), $\psi_k(x)$ for $k = 1, 2, 3, \ldots$ can be determined.

Then by taking the inverse transformation of $[\psi_k(x)]_{k=0}^n$ gives $n$-term approximate solution as

$$ \psi_n(x, t) = \sum_{k=0}^{n} \psi_k(x) t^k, $$

(19)

So, the analytical result of Equation (15) is written as $\psi(x, t) = \lim_{n \to \infty} \psi_n(x, t)$.

**4. Implementation of FRDTM on the CH Equation**

The time-fractional CH Equation (1) in an operator form as

$$ D_t^\alpha \psi + 2c D_x \psi - D_{xx} \psi + 3\psi D_x \psi = 2D_x \psi D_{xx} \psi + \psi D_{xxx} \psi, \quad 0 < \alpha \leq 1, $$

(20)

with IC

$$ \psi(x, 0) = g(x) $$

(21)
Applying FRDTM on Equations (20) and (21), the following recurrence relation is obtained as

\[
\begin{align*}
\Gamma(1+n\alpha+\alpha) \psi_{k+1}(x) &= 2 \sum_{i=0}^{k} \left( \frac{\partial \psi_{i}(x)}{\partial x} \right) \frac{\partial^{2} \psi_{i-1}(x)}{\partial x^{2}} + \sum_{i=0}^{k} \left( \psi_{i} \frac{\partial^{2} \psi_{i-1}(x)}{\partial x^{2}} \right) - 2c \frac{\partial \psi_{i}(x)}{\partial x} + \frac{\partial^{2} \psi_{i}(x)}{\partial x^{2}} \\
-3 \sum_{i=0}^{k} \left( \psi_{i} \frac{\partial \psi_{i-1}(x)}{\partial x} \right) \\
\psi_{0}(x) &= g(x)
\end{align*}
\]  

Solving (22) we obtain

\[
\psi_{1}(x) = \frac{1}{\Gamma(1 + \alpha)} \left[ g(x)g^{3}(x) - 2 \left( c + \frac{3}{2} g(x) - g^{(2)}(x) \right) g^{(1)}(x) \right].
\]  

\[
\psi_{2}(x) = \frac{1}{\Gamma(1 + 2\alpha)} \left[ \begin{array}{c}
\left( g(x) \right)^{2} g^{(6)}(x) + 7g^{(1)}(x)g(x)g^{(5)}(x) + g^{(4)}(x) \\
\left( -4g(x) - 6g^{2}(x) + 13g(x)g^{(2)}(x) + 8g^{(1)}(x) \right)^{2} + 8g(x) \left( g^{(3)}(x) \right)^{2} \\
\left( -21g^{(1)}(x)g^{(5)}(x) \right)^{2} - 30 \left( g^{(1)}(x) \right)^{2} g^{(2)}(x) + 4g^{(2)}(x) \left( c + \frac{3}{2} g(x) \right)^{2}
\end{array} \right].
\]  

Continuing the procedure, likewise, the rest of the components can be evaluated. So the approximate analytical solution of Equation (20) is

\[
\psi(x, t) = \sum_{n=0}^{\infty} \psi_{n}(x)t^{n}.\]

5. Implementation of FRDTM on the mCH Equation

Consider Equation (2) in an operator form as

\[
D_{t}^{4} \psi - D_{xxt} \psi + 3 \psi^{2} D_{x} \psi = 2D_{x} \psi D_{x} \psi + \psi D_{xxt} \psi
\]  

with IC

\[
\psi(x, 0) = p(x),
\]  

Using FRDTM on Equations (26) and (27), the following recurrence relation is obtained as

\[
\begin{align*}
\Gamma(1+n\alpha+\alpha) \psi_{k+1}(x) &= 2 \sum_{i=0}^{k} \left( \frac{\partial \psi_{i}(x)}{\partial x} \right) \frac{\partial^{2} \psi_{i-1}(x)}{\partial x^{2}} + \sum_{i=0}^{k} \left( \psi_{i} \frac{\partial^{2} \psi_{i-1}(x)}{\partial x^{2}} \right) + \frac{\partial^{2} \psi_{i}(x)}{\partial x^{2}} \\
-3 \sum_{i=0}^{k} \sum_{j=0}^{i} \left( \psi_{j} \frac{\partial \psi_{i-j}(x)}{\partial x} \right) \\
\psi_{0}(x) &= p(x)
\end{align*}
\]  

Solving the recurrence relation Equation (28), we get

\[
\psi_{1}(x) = \frac{1}{\Gamma(1 + \alpha)} \left[ p(x)p^{(3)}(x) - 3(p(x))^{2}p^{(1)}(x) + 2p^{(2)}(x)p^{(1)}(x) \right].
\]

\[
\psi_{2}(x) = \frac{1}{\Gamma(1 + 2\alpha)} \left[ \begin{array}{c}
(p(x))^{2}p^{(6)}(x) + 7p^{(1)}(x)p(x)p^{(5)}(x) + p^{(4)}(x) \\
-6(p(x))^{3} + 13p(x)p^{(2)}(x) + 8p^{(1)}(x) \right)^{2} + 8p(x) \left( p^{(3)}(x) \right)^{2} \\
-48p^{(1)}(x)^{2}p^{(3)}(x) \left( p(x) \right)^{2} - \frac{11}{24} p^{(2)}(x) \right)^{3} + \\
\left( -30p(x)p^{(2)}(x)^{2} + 9(p(x))^{2}p^{(2)}(x) - 96p(x) \right) p^{(1)}(x)^{2} \right)^{2} + p^{(4)}(x)x
\end{array} \right].
\]
Similarly, the rest of the components $\psi_3, \psi_4, \ldots$ can be evaluated. So the approximate analytical solution of Equation (26) is

$$\psi(x, t) = \sum_{n=0}^{\infty} \psi_n(x) t^{n\alpha}, \quad (31)$$

6. Implementation of FRDTM on the DP Equation

Considering Equation (3) in operator form, we get

$$D_t^\alpha \psi - D_{xx} \psi + 4\psi^2 D_x \psi = 3D_x \psi D_{xx} \psi + \psi D_{xxx} \psi, \quad (32)$$

with IC

$$\psi(x, 0) = f(x) \quad (33)$$

Applying FRDTM to Equation (32), we obtain

$$\psi_k+1(x) = \frac{\Gamma(1 + n\alpha + k)}{\Gamma(1 + n\alpha)} \psi_k(x) = 3 \sum_{i=0}^{k} \left( \frac{\partial^2 \psi_k(x)}{\partial x^2} \right) + \sum_{i=0}^{k} \left( \frac{\partial^3 \psi_k(x)}{\partial x^3} \right) \frac{\partial \psi_k(x)}{\partial t} \right)$$

Applying FRDTM to Equation (33), we get

$$\psi_0(x) = f(x) \quad (35)$$

Substituting Equation (35) in Equation (34), the following recursive values of $(\psi_n)_{n=1}^{\infty}$ are obtained

$$\psi_1(x) = \frac{1}{\Gamma(1 + \alpha)} \left[ f(x) f^{(3)}(x) - 4(p(x))^2 p^{(1)}(x) + 3p^{(2)}(x)p^{(1)}(x) \right], \quad (36)$$

$$\psi_2(x) = \frac{1}{\Gamma(1 + 2\alpha)} \left[ \begin{array}{c} (f(x))^2 f^{(6)}(x) + 9f^{(1)}(x)f(x)f^{(5)}(x) + f^{(4)}(x) \\ -8f(x)^3 + 18f(x)f^{(2)}(x) + 15\left(f^{(1)}(x)\right)^2 + 11f(x)\left(f^{(3)}(x)\right)^2 \\ -72f^{(1)}(x)f^{(3)}(x)\left(f^{(3)}(x)\right)^2 - \frac{5}{8}f^{(2)}(x)^3 + 9\left(f^{(2)}(x)^3 - 48(f(x))^2 f^{(2)}(x)^2 + 16(f(x))^4 f^{(2)}(x) - 168f(x)\left(f^{(1)}(x)\right)^2 f^{(2)}(x) \\ +64(f(x))^3 \left(f^{(1)}(x)\right)^2 - 24\left(f^{(1)}(x)\right)^4 \end{array} \right]. \quad (37)$$

Continuing in this manner $\psi_3, \psi_4, \ldots$ can be evaluated. So the approximate analytical solution of Equation (32) is

$$\psi(x, t) = \sum_{n=0}^{\infty} \psi_n(x) t^{n\alpha} \quad (38)$$

7. Results and Discussion

In this section, approximate solutions of displacement $\psi(x, t)$ for different values of $\alpha$ are calculated for different values of $t$ and $x$ at fixed $c = 0.005$ and $k = 0.5$. In Section 4, IC [24,28] is considered as $\psi(x, 0) = g(x) = (k + c)e^{-|x|} - c$ for showing the nature of the displacements of CH Equation (1). The solutions $\psi(x, t)$ for different values of $t$, $x$ and $\alpha$ are depicted in Figure 1a–d for the CH equation. In Section 5, we considered the IC [11] as $\psi(x, 0) = p(x) = -2\operatorname{sech}^2\left(\frac{x}{2}\right)$, a particular case for viewing the behavior of the displacements. The numerical results of $\psi(x, t)$ for various values of $t$, $x$ and $\alpha$ are portrayed in Figure 2a–d for the mCH Equation (2). Similarly, in Section 6, the IC [11] is assumed as $\psi(x, 0) = f(x) = -\frac{15}{8}\operatorname{sech}^2\left(\frac{x}{2}\right)$ for presenting the nature of the displacements. The numerical solutions $\psi(x, t)$ for various values of $t$, $x$ and $\alpha$ are illustrated in Figure 3a–d for the DP Equation (3). Also,
comparison tests have been included among the existing solution and the results of Zhang et al. [11] and Zhang et al. [28] in Figures 4–9. One may see from Tables 2–4 that approximate solutions solved by FRDTM are quite close to the solutions solved by Zhang et al. [11,28].

8. Conclusions

In this article, FRDTM is successfully implemented for solving time-fractional CH, mCH, and DP equations with suitable initial conditions. Solutions are obtained without any transformation and perturbation. Three test problems were performed to validate the precision and efficacy of the current method. Also, it was seen that the obtained results are a good agreement with the solution obtained by Zhang et al. [11,28]. The main benefit of this approach is that linearization is not required for this method and therefore it reduces complex numerical computations significantly compared to the other existing methods such as the perturbation technique, DTM, and ADM. Small size computations over other techniques are the main advantages of the proposed method.

Author Contributions: Each author has contributed equally to prepare and finalize the whole research work of the present paper.

Funding: This research received no external funding.

Acknowledgments: The first author is grateful to the Department of Science and Technology, Govt. of India for providing an INSPIRE fellowship (IF170207) to do the current research.

Conflicts of Interest: The authors declare that there are no conflicts of interests.
