Abstract: Abundantly available biomass wastes from agriculture can serve as effective environmental remediation materials. In this study, activated biochar was fabricated from macadamia nutshell (MCN) through carbonization and chemical modification. The resultant biochars were used as adsorbents to remove toxic metal ions such as Cu$^{2+}$ and Zn$^{2+}$ from aqueous solutions. The results showed that the activated MCN biochar has a high adsorption capacity for toxic metal ions. When MCN biochar was activated with K$_2$CO$_3$, the adsorption efficiencies for Cu$^{2+}$ and Zn$^{2+}$ were 84.02% and 53.42%, respectively. With H$_3$PO$_4$ activation, the Cu$^{2+}$- and Zn$^{2+}$-adsorption performances were 95.92% and 67.41%, respectively. H$_2$O$_2$-modified MCN biochar had reasonable Cu$^{2+}$- and Zn$^{2+}$-adsorption efficiencies of 79.33% and 64.52%, respectively. The effects of pH, adsorbent concentration and adsorption time on the removal performances of Cu$^{2+}$ and Zn$^{2+}$ in aqueous solution were evaluated. The results exhibited that the activated MCN biochar showed quick adsorption ability with an optimal pH of 4 and 4.5 for both Cu$^{2+}$ and Zn$^{2+}$, respectively.

Keywords: toxic metals removal; biochar; macadamia nutshell; adsorption; activated carbon

1. Introduction

The rapid and continuous growth of industrialization and urbanization has caused serious environmental problems. Of these, contamination of water sources with toxic metals has attracted considerable interest from scientists and governments worldwide. Toxic metal ions—even at trace levels—can be extremely harmful to human health and ecosystems [1,2]. Therefore, the removal of toxic metal ions from aqueous solutions requires urgent attention. Many techniques have been effectively used for the removal of toxic metals ions from polluted wastewater, including, but not limited to, precipitation, use of filtration membranes, chemical treatment, reverse osmosis, electrochemical treatment and adsorption [3–5]. Among these methods, adsorption has been demonstrated as an effective pathway for the removal of toxic ions from contaminated water because of its low operation cost, high performance and simplicity.
Many materials and resources have been employed as adsorbents. For example, biomass waste, industrial waste, carbon-based nanomaterials, oxides, natural and synthetic polymers and surfactants have been used for remediation of toxic metal contamination [6–8]. Biochar, a common carbon-based group of nanomaterials derived from biomass, has a microporous structure with high surface area, many reactive sites on the surface and high adsorption capacity [9], and therefore, it is extensively used as an effective and affordable adsorbent of metal ions [10]. Biochar is obtained from the thermochemical decomposition of biomass [11,12]. The factors that decide the quality of biochar products are heat treatment time, temperature, type of natural resources and limited oxygen condition [13]. Abundant natural wastes such as cocoa husks, corn cob, rice husks, sludge, coconut shell, seeds, fruits, straws, leaves, orange peel, and other residuals are used to produce biochar for the effective removal of toxic metal ions [14–16].

The macadamia nut was first discovered in Southern Australia by botanists in 1857, and thereafter, it has been widely grown worldwide as a high-value agricultural product. Approximately 70–77% of a macadamia nut is the nutshell, which means that one ton of macadamia kernel produces an average of approximately three tons of nutshell [17]. With an annual estimated production of 44,000 tons of macadamia kernels, more than 120,000 tons of macadamia nutshell are discarded as solid waste per annum. This large amount of solid waste needs to be treated—or could be used for various applications [18]. One of the important recycling processes of macadamia nutshell is to produce biochar, which is used as activated carbon for adsorption or charcoal for heating purposes [19,20]. With high surface area and carbon content, the carbon material produced from the macadamia nutshell is of lower ash content than that of other biomass materials. Macadamia-derived biochar has been successfully employed in various applications such as when combined with other types of biochars to form denitrification agents in bioreactors [21], for soil amendment and nutrient control in agriculture [22,23] and for the production of steel [24]. In order to enhance the surface area of the biochar, which increases the adsorption capacity, the biochar has to activate either by physical or chemical methods. Among these, chemical activations. Among these, chemical activation is one of the most favorites techniques to obtain the desirable adsorption capability of biochar for the pollutant treatment in practical [25,26]. Rodrigues et al. also fabricated activated carbon from macadamia nutshell and used it as an adsorbent for the effective removal of organic solvents such as phenol [27]. The macadamia-based biochars were also successfully employed for the removal of toxic metal ions [28–32]. However, the application of macadamia nutshell-derived biochar solely for the removal of Zn$^{2+}$ and Cu$^{2+}$ seems to be scarce. Furthermore, the need for finding an effective activation and/or chemical modification protocol to produce activated carbon from the macadamia nutshell is crucial.

Thus, this work presents an effective protocol to fabricate chemically modified biochar from macadamia nutshells through carbonization and chemical activation. In these works, the common and widely available basic chemicals such as K$_2$CO$_3$, H$_3$PO$_4$ and H$_2$O$_2$ were used to activate the MCN biochar. The resultant biochar is employed as an adsorbent for the removal of Cu$^{2+}$ and Zn$^{2+}$ from an aqueous solution. The effects of several factors on the adsorption performance such as pH of the solution, concentration, and adsorption time were investigated in detail.

2. Materials and Methods

2.1. Materials

Stock solutions of Cu$^{2+}$ and Zn$^{2+}$ with concentrations of 30 ppm each, K$_2$CO$_3$, H$_3$PO$_4$ and H$_2$O$_2$ were purchased from Xilong Scientific Co., Ltd., Shantou, China. Macadamia nutshells (MCN) were obtained as biomass waste from the Lam Dong Province, Vietnam. All chemicals (except macadamia nutshells) were used as received without any purification.
2.2. Fabrication of Modified MCN Biochar from Macadamia Nutshells

Macadamia nutshells were collected as biomass waste and then washed thoroughly and dried before the carbonization process. Typically, MCN nutshells with uniform size were cleaned and thoroughly rinsed with distilled water, then dried at a temperature of 110 °C for 48 h. After primary treatment, the MCN nutshells were calcined at a temperature of 350 °C for 1 h with a heating rate of 23 °C per minute to form MCN charcoal.

**K$_2$CO$_3$-modified MCN biochar:** MCN charcoal was immersed and agitated in K$_2$CO$_3$ solution with a charcoal:K$_2$CO$_3$:water ratio of 1:1:10 for 24 h. The precipitate was filtered and dried at 110 °C for 24 h. The K$_2$CO$_3$-modified MCN charcoal was then carbonized in the furnace for 1 h at a temperature of 650 °C. The obtained samples were washed thoroughly with distilled water until the pH reached 7 and then dried at 110 °C. Samples were ground to fine particles and stored in a vacuum for further characterization.

**H$_3$PO$_4$-modified MCN biochar:** MCN charcoal was immersed and agitated in H$_3$PO$_4$ solution for 24 h with a charcoal:H$_3$PO$_4$:water ratio of 1:1:10. The precipitate was filtered and dried at 170 °C for 1 h. The K$_2$CO$_3$-modified MCN charcoal was then carbonized in the furnace for 1 h at a temperature of 500 °C. The obtained samples were washed thoroughly with distilled water until the pH reached 7, then they were dried at 110 °C. Samples were ground to fine particles and stored in a vacuum for further characterization.

**H$_2$O$_2$-modified MCN biochar:** MCN charcoal was immersed and agitated in H$_2$O$_2$ 25% solution continuously for 48 h with charcoal:H$_2$O$_2$ 25% ratio of 1:10. After modification, the samples were washed with distilled water until neutral pH and dried at a temperature of 110 °C. Samples were ground to fine particles and stored in a vacuum for further characterization.

2.3. Toxic Metal Adsorption Studies

**Effect of pH of the solution:** The toxic metal ions employed in this study were Cu$^{2+}$ and Zn$^{2+}$ with a concentration of 30 ppm each. In the typical experiment, the modified-MCN biochar with a concentration of 0.3 g/L was added to 50 mL of Cu$^{2+}$ or Zn$^{2+}$ 30 ppm with the pH of the solution adjusted from 2.5 to 5.5. The adsorption time was 1 h. The precipitates were separated, and the residual was used to measure the remaining ions in the solution. The experiments were repeated three times.

**Effect of biochar content:** The modified-MCN biochar with the concentration ranging from 0.2 g/L to 2 g/L was added to 50 mL of Cu$^{2+}$ or Zn$^{2+}$ 30 ppm with the pH of the solution of 5.5. The adsorption time was 1 h. The precipitates were separated, and the residual was used to measure the remaining ions in the solution. The experiments were repeated three times.

**Effect of adsorption time (adsorption kinetics):** The modified-MCN biochar with the concentration of 0.3 g/L was added to 50 mL of Cu$^{2+}$ or Zn$^{2+}$ 30 ppm with the pH of the solution of 5.5. The adsorption time was from 0 min to 120 min. The precipitates were separated, and the residual was used to measure the remaining ions in the solution. The experiments were repeated three times.

2.4. Characterization of Biochars

The infrared absorption spectrum determines the FT-IR molecular functional group using the PerkinElmer spectrophotometer with a resolution of 2 cm$^{-1}$ and 16 scans (PerkinElmer, Inc., Waltham, MA, USA). All the spectra were recorded in the transmittance mode [33]. SEM particle size measurement and surface observation were conducted using a scanning electron microscope (SEM; JEOL, Ltd., Tokyo, Japan) at 2.0 kV and 10 µA. The samples were coated with gold powder before the images were captured. pH was measured directly using a pH meter (Mettler Toledo—S220K, Mettler Toledo, Greifeensee, Switzerland).
3. Results and Discussion

3.1. SEM Image and FTIR Spectrum of the Modified-MCN Biochar

The morphology of the prepared modified-MCN biochar was observed using SEM and the result is shown in Figure 1a. It is evident that the prepared modified-MCN biochar has a porous microstructure with an average pore size of 10 µm. The appearance of the pore structures is due to the etching caused by the activating agent such as H₃PO₄ as well as the activating condition at high temperatures. The chemical surface properties of the resultant biochar were investigated using an FTIR spectrum (Figure 1b). In the FTIR spectrum, the appearance of the vibration bands at 700 cm⁻¹ and 400 cm⁻¹ represents the stretching oscillation of the C=C functional group, which indicates that the C content increases in the biochar [34]. The vibration band at the wavelength of 3426.4 cm⁻¹ is ascribed to the OH⁻ stretching in the functional hydroxyl group, which is favorable for the metal ion adsorption [35]. The functional carbonyl groups (C–O and C=O) on the surface of biochar are also observed in the wavelength range of 1000 cm⁻¹ to 2000 cm⁻¹ of the FTIR spectrum, which indicates that the surface of the MCN biochar was successfully modified with the functional groups thereby improving the adsorption capability of the MCN biochar. The surface area of the modified-MCN biochar was determined to be 339.262 m²/g, which is reasonable for adsorption application.

![Figure 1.](image)

3.2. Adsorption of Cu²⁺ by Modified-MCN Biochar

It is well-known that the pH of the solution plays a significant role in the adsorption behavior of the Cu²⁺, which is related to the dissolution and precipitation of copper [36]. With a pH of less than 6, copper is mostly present in the aqueous solution as ions, however, when the pH of the solution >6, copper ions tend to precipitate [37]. Thus, to study adsorption behavior, the pH of the solution of <6 was selected. Figure 2 presents the Cu²⁺ adsorption performance by the modified-MCN biochars with various pH values of the solution for one hour with the adsorbent dose of 0.3 g/L. The figure clearly shows that the adsorption capabilities of Cu²⁺ by MCN biochars modified with K₂CO₃, H₃PO₄ and H₂O₂ increases along with an increase in the pH of the solution. The Cu²⁺ removal percentages significantly increased from the pH of the solution of 2.5 to 4. Further, an increase in pH from 4–5.5 witnesses a negligible increase in adsorption efficiencies. For the K₂CO₃-modified MCN biochar, the removal percentages of Cu²⁺ at pH values of 4, 4.5, 5 and 5.5 were 22.66%, 28.27%, 32.61% and 33.85%, respectively, indicating that the optimal pH for Cu²⁺ removal by the K₂CO₃-modified MCN biochar was 5–5.5. When Cu²⁺ was absorbed by H₃PO₄-modified MCN biochar, a similar trend in the effect of pH on the adsorption performance was also observed and the maximum adsorption of ions was 55% obtained at a pH of 5–5.5. Therefore, a pH of the solution of 5.5 was optimal for the maximum Cu²⁺ adsorption of 76%. These results are consistent with that of previous studies [38,39]. It is relevant to
note that the MCN biochar modified by H$_2$O$_2$ showed the highest Cu$^{2+}$ removal in comparison with that modified by K$_2$CO$_3$ and H$_3$PO$_4$.

![Figure 2](image2.png)

**Figure 2.** Effect of pH of the solution on Cu$^{2+}$ adsorption by chemically modified MCN biochars at the adsorbent dose of 0.3 g/L and adsorption time of one hour.

The concentrations of the adsorbents had significant impacts on the Cu$^{2+}$ and Zn$^{2+}$ adsorption performances of the activated biochar. Figure 3 shows the Cu$^{2+}$ adsorption efficiency of chemically modified MCN biochars with a pH of the solution of 5 and an adsorption time of 1 h. The adsorption capacities of MCN biochars activated with K$_2$CO$_3$, H$_2$O$_2$ and H$_3$PO$_4$ increased along with adsorbent concentrations. For the K$_2$CO$_3$-activated MCN biochar, the Cu$^{2+}$ adsorption efficiency increased remarkably with dosed of 0.2–1.4 g/L. It gradually increased with dosage before reaching the maximum of 84.96% of Cu$^{2+}$ removal at the adsorbent concentration of 2 g/L. Similar trends could also be observed with H$_2$O$_2$ and H$_3$PO$_4$-activated MCN biochars, where the Cu$^{2+}$ adsorption efficiencies increase with an increase of adsorbent concentrations and reaching a maximum of 80.50% and 94.53% at a concentration of 2 g/L H$_2$O$_2$ and H$_3$PO$_4$-activated MCN biochars, respectively. With the dose of 2 g/L, the MCN biochars modified with H$_3$PO$_4$ exhibited the highest Cu$^{2+}$ removal efficiency in comparison with that modified with H$_2$O$_2$ and K$_2$CO$_3$.

![Figure 3](image3.png)

**Figure 3.** Effects of concentration of chemically modified MCN biochars on Cu$^{2+}$ adsorption performance with an adsorption time of one hour and pH of the solution of 5.
Figure 4 shows the effect of adsorption time on the Cu\(^{2+}\) removal efficiencies by the modified MCN biochars with an adsorbent content of 2 g/L, Cu\(^{2+}\) concentration of 30 ppm and solution pH of 5. It can be clearly seen that the optimal time to adsorb Cu\(^{2+}\) by the MCN biochars activated with K\(_2\)CO\(_3\) was 30 min with an efficiency of 84.02%, which became saturated at 40 min of processing time at a removal efficiency of 86.35%, after which the treatment efficiency increased insignificantly at 50 min to 87.85% and slightly decreased at 1 h to 87.81%. Research results determined that pH = 5, a dosage of 2 g/L, and a processing time of 30 min was optimal for treating Cu\(^{2+}\). Thus, it shows that K\(_2\)CO\(_3\)-activated MCN biochar could be used effectively as an adsorbent for the treatment of toxic Cu\(^{2+}\) in textile wastewater. Badruddoza et al. (2011) [33] found that that after 30 min of treatment, the processing efficiency of Cu\(^{2+}\) using carboxymethyl-cyclodextrin conjugated magnetic nanoparticles had a similar treatment performance of 90% removal. Research results from Singha and Das (2013) [40] showed that after 5 h of treatment, the efficiency of Cu\(^{2+}\) treatment at pH 6 using activated carbon from coconut shell was approximately 90%.

![Figure 4](image.png)

Figure 4. Effect of adsorption time on Cu\(^{2+}\) removal efficiencies using activated MCN biochars with an adsorbent dose of 2 g/L at a solution pH of 5.

For the MCN biochar modified with H\(_3\)PO\(_4\) the Cu\(^{2+}\) removal efficiencies with reaction times of 0, 10, 20, 30, 40, 50 min and one hour were determined to be 0, 85.08%, 92.58%, 93.21%, 95.92%, 96.12%, 96.14% and 96.03%, respectively. This indicates that the H\(_3\)PO\(_4\)-activated MCN biochar has a quick absorbing capability for Cu\(^{2+}\) with the highest efficiency of 96.14% after 50 min of adsorption time. When activated with H\(_2\)O\(_2\), the MCN biochar also reveals fast removal of Cu\(^{2+}\) as 51.58% is removed only after 10 min. The optimized adsorption time for Cu\(^{2+}\) treatment using H\(_2\)O\(_2\)-activated MCN biochar is one hour with the highest Cu\(^{2+}\) removal efficiency of 80.9%. It can be concluded that the MCN biochar activated with H\(_3\)PO\(_4\) and K\(_2\)CO\(_3\) show faster Cu\(^{2+}\) adsorption efficiencies than that activated with the H\(_2\)O\(_2\) agent.

3.3. Adsorption of Zn\(^{2+}\) by Modified-MCN Biochar

The pH of the solution had a significant effect on Zn\(^{2+}\) adsorption performance of biochar. Thus, the effect of pH of the solution on the removal efficiency of Zn\(^{2+}\) by the modified-MCN biochar for one hour with the adsorbent dose of 0.3 g/L was investigated as shown in Figure 5. In general, the adsorption capabilities of Zn\(^{2+}\) by MCN biochars modified with K\(_2\)CO\(_3\), H\(_3\)PO\(_4\), and H\(_2\)O\(_2\) decreased at a low pH of the solution of 2 to 3, reached a minimum value at a pH 2.5–3, then significantly increased in a pH of 3.5–5. The adsorption of Zn\(^{2+}\) by MCN biochars activated with K\(_2\)CO\(_3\) decreased with the increase in the pH of the solution from 2 to 3 and reached a minimal removal concentration of 2.63 ppm at a pH of...
3. Further increases in the pH of the solution demonstrated an increase in the adsorption capabilities of biochar; it reached a maximum at the pH of 4.5 with a removal concentration of 4.85 ppm. A similar trend was also observed with the adsorption behaviors of the H₂O₂-modified biochar with the change in the pH of the solution from 2 to 5. A Zn²⁺ removal concentration of 2.18 ppm was achieved at a pH of 3 and a maximum of 6.27 ppm at a pH of 4.5. Interestingly, for the H₃PO₄-activated macadamia biochar, the lowest Zn²⁺ removal concentration was observed to be 1.33 ppm at the pH of 2.5 and the highest removal efficiency was at the pH of 4.5 with a removal concentration of 6.05 ppm. These results indicate that the most suitable pH solution for the removal of Zn²⁺ from the aqueous solution by activated macadamia biochar was around 4.5 and the H₂O₂-activated biochar reveals the highest Zn²⁺ adsorption capability.

![Figure 5](image-url)  
**Figure 5.** Effect of pH of the solution on Zn²⁺ adsorption by chemically modified MCN biochars with an adsorbent dose of 0.3 g/L and adsorption time of one hour.

Figure 6 shows the effect adsorbent concentrations of the chemically modified MCN biochars on the removal performance of Zn²⁺ from the aqueous solution at a pH of 4.5 for one hour. The Zn²⁺ removal concentrations increased with the increase in adsorbent dosed. For the K₂CO₃-activated biochar as adsorbent, Zn²⁺ removal increased significantly in the adsorbent doses ranging from 0.2 g/L to 2 g/L and reaches a maximum at the adsorbent dose of 2 g/L with the highest removal percentage of 45.80%. However, compared to the removal efficiency of 1.8 g/L (45.29%), this value was not significant, and thus, the optimal K₂CO₃-activated biochar concentration for cost-effective adsorption of Zn²⁺ adsorption was determined to be 1.8 g/L. This trend was also observed with H₂O₂ and H₃PO₄-activated MCN biochars as the optimal adsorbent doses were determined to be 1.8 g/L for Zn²⁺ adsorption efficiencies of 57.3% and 65.56%, respectively.

Figure 7 shows the effect of adsorption time (0 min to 120 min) on the Zn²⁺ removal efficiencies of the chemically modified MCN biochars with the adsorbent content of 1.8 g/L, Zn²⁺ concentration of 30 ppm, and a pH of 4.5. Unlike the removal of Cu²⁺, for which the chemically activated macadamia biochars showed high adsorption speed reaching the equilibrium state only after 30 min, in this case, the adsorption ability of the biochars for Zn²⁺ oxides were relatively slow. The Zn²⁺ adsorption efficiencies of K₂CO₃, H₂O₂ and H₃PO₄-modified macadamia biochars only reached the equilibrium value after 80 min of adsorption time with the removal concentrations of 12.22 ppm, 15.48 ppm and 16.42 ppm, respectively.
The adsorption capacity of the biochar fabricated from the rice husk for the Cu\(^{2+}\) and Zn\(^{2+}\) removal [41].

The results discussed above lead to the conclusion that the macadamia biochars activated with H\(_3\)PO\(_4\) show the highest and fastest Zn\(^{2+}\) and Cu\(^{2+}\) adsorption performances, and therefore, can be employed as effective adsorbents for the removal of metal ions from aqueous media.

It is clear from the above results that the MCN biochars activated with H\(_3\)PO\(_4\) reveal the highest removal efficiency toward Cu\(^{2+}\) and Zn\(^{2+}\). The adsorption capacity can be roughly estimated with the following equation:

\[
q_e = \frac{(C_0 - C_e) \times V}{m}
\]  

where \(C_0\) (mg/L) is the initial concentration, \(C_e\) (mg/L) is the equilibrium concentration, \(V\) (L) is the solution volume and \(m\) (g) is the mass of the activated MCN biochars. Based on the investigation of adsorbent dosage on the removal efficiency toward Cu\(^{2+}\) and Zn\(^{2+}\) with the adsorption dosage of 0.2 g/L, Cu\(^{2+}\) and Zn\(^{2+}\) concentration of 30 mg/L, the adsorption capacity of activated MCN biochars for Cu\(^{2+}\) and Zn\(^{2+}\) are 2.825 and 2.1 mg/g, respectively. These results are slightly higher than the adsorption capacity of the biochar fabricated from the rice husk for the Cu\(^{2+}\) and Zn\(^{2+}\) removal [41].
4. Conclusions

To summarize, the macadamia biochar was successfully fabricated and modified with K$_2$CO$_3$, H$_2$O$_2$ and H$_3$PO$_4$. The modified-MCN biochars have porous microstructures with an average pore size of 10 µm. The resultant chemically modified biochars were used as adsorbent and they show high Cu$^{2+}$ and Zn$^{2+}$ adsorption performances. The effect of several factors such as the pH of the solution, adsorption time and adsorbent doses were investigated in detail. The results showed that the optimized pH of the solution, adsorbent doses and adsorption time for the removal for Cu$^{2+}$ and Zn$^{2+}$ are 5, 2 g/L and 30 min and 4.5, 1.8 g/L and 80 min, respectively. Of the three K$_2$CO$_3$, H$_2$O$_2$ and H$_3$PO$_4$ modifiers, the macadamia biochars activated with H$_3$PO$_4$ had the highest Cu$^{2+}$ and Zn$^{2+}$ adsorption performances. With high adsorption efficiencies and inexpensive fabrication from biomass waste, chemically activated macadamia biochar can be used as a promising adsorbent for the effective removal of toxic metal ions in practical applications.
