Supplementary Materials: ACP-TX-I and ACP-TX-II, Two Novel Phospholipases A2 Isolated from Trans-Pecos Copperhead *Agkistrodon contortrix pictigaster* Venom: Biochemical and Functional Characterization

Salomón Huancahuire-Vega, Luciana M. Hollanda, Mauricio Gomes-Heleno, Edda E. Newball-Noriega and Sergio Marangoni

**Figure S1.** Re-chromatography on an analytical RP-HPLC C18 analytical column of ACP-TX-I (A) and ACP-TX-II (B). Protein elution employed a linear gradient (0–66.5%) of acetonitrile at a flow rate of 1.0 mL/min. Elution was monitored at 280 nm.
Figure S2. ACP-TX-II produces local myotoxicity when injected intramuscularly, but little systemic myotoxicity when injected intravenously, whereas ACP-TX-I and crude venom injected intravenously produce no systemic myotoxicity. 100 µg of *A. contortrix pictigaster* venom (WV), ACP-TX-I and ACP-TX-II dissolved in 100 µL of PBS were injected intravenously (IV) in mice (tail vein). The control group received 100 µL of PBS. Blood was collected from the tail into heparinized capillary tubes 3 h after administration of venom and toxins and plasma creatine kinase activity (CK in U/L) was determined. Plasma CK levels did not increase significantly compared to control. For comparison, the last column represents the an intramuscular injection (IM) of the same concentration of ACP-TX-II, the increased plasma CK levels above 1000 U/L. Each column represent means ± SD of four mice per group. (* p < 0.05).
