Abstract: A dc/dc pulse width modulation (PWM) circuit was investigated to realize the functions of reduced primary current loss and balanced voltage and current distribution. In the presented dc/dc converter, two full bridge pulse width modulation circuits were used with the series/parallel connection on the high-voltage/low-voltage side. The flying capacitor was adopted on the input side to achieve voltage balance on input split capacitors. The magnetic coupling element was employed to achieve current sharing between two parallel circuits. A capacitor-diode passive circuit was adopted to lessen the primary current at the commutated interval. The phase-shifted duty cycle control approach was employed to regulate load voltage and implement soft switching characteristics of power metal-oxide-semiconductor field-effect transistors (MOSFETs). Finally, the experimental results using a 1.68 kW prototype converter were obtained to confirm the performance and feasibility of the studied circuit topology.

Keywords: dc converter; full bridge converter; zero voltage operation

1. Introduction

High power density/efficiency dc/dc converters [1,2] have been proposed to reduce unnecessary power loss in order to reduce environmental pollution and meet global energy demands. Clean and renewable energy sources meet these requirements to provide available ac or dc power to ac utilities, dc micro-grids, residential houses and commercial buildings by using power electronic based converters or inverters. High-voltage pulse width modulation (PWM) converters have been presented for industry power units [3,4], dc micro-grid systems [5–7] and dc traction or dc light rail transportation systems [8,9]. For these applications, the dc bus voltage is regulated between 750 V and 800 V. Full bridge circuits with a high switching frequency high-voltage rating SiC MOSFET or high-voltage rating insulated gate bipolar transistor (IGBT) devices can be adopted for high dc voltage applications. However, 1200 V SiC MOSFET devices are expensive and 1200 V IGBT devices have low switching frequency problems. Cost and performance are always the two main issues in the development of the available and high reliability power converters. Therefore, MOSFET power devices have been widely adopted in high efficiency power electronics. To improve the low-voltage drawback of MOSFETs in high-voltage applications, zero voltage switching, multi-level circuit topologies [10–14] have been developed and proposed to decrease conduction and switching losses. The phase shift pulse width modulation (PSPWM) and frequency modulation have normally been adopted to regulate duty cycle or switching frequency. However, the main disadvantage of conventional PSPWM is high circulating current losses at low effective duty cycle. In order to reduce circulating current, an active or passive snubber used on the low-voltage side has been proposed in [15–17]. A modular dc/dc converter [18] using low power rating modular circuits in series or parallel connection has been proposed to increase circuit efficiency and power rating. However, the current between each modular circuit may be
unbalanced. To accomplish current balance issue, several current balancing approaches have been presented in [19,20].

A series/parallel-connected dc/dc converter is proposed to accomplish reduced primary circulating current, a soft switching operation, and balanced input voltages and output currents. Two full bridge circuits with series/parallel connection on input/output side are used in the studied circuit to achieve voltage and current sharing for the high voltage input and current output. Therefore, power devices on each full bridge circuit have \( V_{\text{in}}/2 \) voltage stress. To prevent input split voltages imbalance, a voltage balance capacitor was used on the input side to automatically achieve split voltages balance. Passive snubber circuits were employed on output side to create a positive voltage on the secondary rectified terminal under the commutated state so that the primary current at the commutated state can be reduced. To realize current sharing of two full bridge circuits, a current-balance magnetic component was adopted on the high-voltage side. If two currents are unbalanced, then one induced voltage of MC component is decreased to lessen the larger converter current. Therefore, two converter currents can be compensated automatically. PSPWM was adopted to control power devices and accomplish soft switching operation of active switches. The organization of this paper is as follows: The circuit structure and the principle of operation are discussed in Section 2. The steady state operation of the presented converter is shown in Section 3. Test results with a laboratory prototype are presented and investigated in Section 4. The conclusions of the studied converter are discussed in Section 5.

2. Circuit Structure and Principle of Operation

High-voltage converters were researched and presented for industry power supplies, dc traction vehicle and dc micro-grid systems. Ac/dc power converters with low harmonic currents, high power factor (PFC) and a stable dc voltage shown in Figure 1a are required for industry power converters. Normally, the dc voltage \( V_{\text{in}} \) is controlled at 760 V. Then, a high-frequency link converter is adopted to provide low-voltage output. Figure 1b illustrates the basic power distributed diagrams on dc light rail vehicle. A high-voltage dc converter can convert a 760 V input to supply a low-voltage output for battery charger, control, and communication demands. Figure 1c demonstrates the blocks of a bipolar dc micro-grid system to integrate ac utility system, clean energy generators and industry load and residential load into a common dc bus voltage.

Figure 2 gives the converter configuration of the developed circuit with series/parallel connection of full bridge circuits to achieve low circulating current loss, soft switching for power MOSFETs, and balanced input split voltages and output current sharing. The first full bridge circuit has power MOSFETs \( S_1-S_4 \) with the output capacitors \( C_1-C_4 \), leakage or external inductor \( L_{\text{r}1} \), transformer \( T_{\text{r}1} \), magnetic core \( MC \), filter inductor \( L_{\text{o}1} \), secondary-side rectifier diodes \( D_1 \) and \( D_2 \), and passive circuit including \( C_{\text{a}1}, D_{\text{a}1} \) and \( D_{\text{b}1} \). Likewise, the second full bridge circuit includes the components \( S_5-S_8, C_5-C_8, L_{\text{r}2}, T_{\text{r}2}, MC, L_{\text{o}2}, D_3, D_4, C_{\text{a}2}, D_{\text{a}2} \) and \( D_{\text{b}2} \). \( C_{\text{in}1} \) and \( C_{\text{in}2} \) are input split capacitors and \( C_b \) is the balance capacitor. Each circuit can transfer one-half rated power to the secondary side. The magnetic core [20] is used to balance \( i_{LR1} \) and \( i_{LR2} \). Under the balanced primary currents (\( |i_{LR1}| = |i_{LR2}| \)), the induced voltages \( V_{L1} \) and \( V_{L2} \) are zero. If \( i_{LR1} \) and \( i_{LR2} \) are unbalanced (such as \( |i_{LR1}| > |i_{LR2}| \)), the induced voltage \( V_{L1} \) of MC cell is decreased in order to decrease \( i_{LR1} \) and \( V_{L2} \) is increased to increase \( i_{LR2} \). Thus, \( i_{LR1} \) will equal \( i_{LR2} \) and \( V_{L1} = V_{L2} = 0 \). PSPWM is used to control \( S_1-S_8 \) and have zero voltage switching on the MOSFETs. Power switches \( S_1-S_4 \) and \( S_5-S_8 \) have identical PWM waveforms. The balance capacitor \( C_b \) is linked between points \( a \) and \( c \). If \( S_1 \) and \( S_5 \) are on and \( S_2 \) and \( S_6 \) are off, then \( V_{Ch} = V_{Ch1} \). Likewise, \( V_{Ch} = V_{Ch2} \) if \( S_2 \) and \( S_6 \) are on and \( S_1 \) and \( S_5 \) are in the off. Since the duty cycle \( d_{S1} = d_{S2} = 0.5 \), it is obvious that \( V_{Ch} = V_{Ch1} = V_{Ch2} = V_{in}/2 \). Thus, the drain voltages of \( S_1-S_8 \) are \( V_{in}/2 \). To decrease the primary-side circulating currents, passive snubbers, \( C_{a1}, D_{a1}, D_{b1}, C_{a2}, D_{a2}, D_{b2} \) are used on the presented circuit. At the same time, the filter inductor voltages \( v_{Lo1} = v_{Ca1} - V_o \) and \( v_{Lo2} = v_{Ca2} - V_o \) rather than \( -V_o \) in the traditional full bridge duty cycle converters.
A series/parallel-connected dc/dc converter is proposed to accomplish reduced equipment and communication demands. Due to the switching states of power devices, the converter has fourteen steps in a full bridge configuration. At the switching states (1), the voltage across the output capacitor \( V_{o2} = V_{ss} \); (2) \( V_{o2} = 0 \); (3) \( V_{o2} = V_{ss} \); (4) \( V_{o2} = 0 \); (5) \( V_{o2} = V_{ss} \); (6) \( V_{o2} = 0 \); (7) \( V_{o2} = V_{ss} \); and (8) \( n_1 = n_2 = n \). Figure 3 shows the PWM waveforms of the studied converter. The duty cycle of \( S_1 \sim S_5 \) is 0.5. The gating signals of \( S_4 \) (\( S_3 \)) is shifted to \( S_1 \) (\( S_2 \)), respectively. Due to the switching states of power devices, the converter has fourteen steps in a full bridge configuration.
switching period. The PWM waveforms are symmetrical for every half cycle. Therefore, only the first seven steps are discussed and the circuits of first seven operating steps are illustrated in Figure 4.

\[
(L_{r1} + n_1^2 L_{o1})i_{r1}^2(t_0) \geq C_{oss} V_{in}^2 / 2
\]

(1)

\[
(L_{r2} + n_2^2 L_{o2})i_{r2}^2(t_0) \geq C_{oss} V_{in}^2 / 2
\]

(2)

If these conditions are satisfied, then \(v_{C1} = v_{C5} = V_{in/2}\) and \(v_{C2} = v_{C6} = 0\) at \(t_1\). The time duration in step 1 is obtained in Equation (3).

\[
\Delta t_{01} = t_1 - t_0 = \frac{C_{oss} V_{in}}{i_{r1}(t_0)} = \frac{n_1 C_{oss} V_{in}}{i_{Lo,peak}} \approx \frac{2n_1 C_{oss} V_{in}}{I_o}
\]

(3)

The time duration \(\Delta t_{01}\) is related to the load current and input voltage.

**Step 2** \([t_1, t_2]\): At \(t_1\), \(v_{C2} = v_{C6} = 0\). The positive primary currents \(i_{r1}\) and \(i_{r2}\) will flow through the body diode of \(S_2\) and \(S_6\). Thus, power MOSFETs \(S_2\) and \(S_6\) can achieve zero-voltage switching after \(t_1\). The ac side voltages \(v_{ab} = v_{cd} = 0\) and \(i_{r1}\) and \(i_{r2}\) decrease. Therefore, \(D_{a1}\) and \(D_{a2}\) conduct at this freewheeling state. The magnetizing voltages \(v_{l,m1}\) and \(v_{l,m2}\) are clamped at \(v_{Ca1}\) and \(v_{Ca2}\), respectively. The primary inductor voltages \(v_{Lr1} = -n_1 v_{Ca1}\) and \(v_{Lr2} = -n_2 v_{Ca2}\) and the filter inductor voltages \(v_{Lo1} = v_{Ca1} - V_o < 0\) and \(v_{Lo2} = v_{Ca2} - V_o < 0\). Therefore, \(i_{r1}, i_{r2}, i_{Lo1}\) and \(i_{Lo2}\) are all decreased in this step.

\[
i_{r1}(t) \approx \frac{n_1 v_{Ca1}}{L_{r1}}(t - t_1)
\]

(4)

\[
i_{r2}(t) \approx \frac{n_2 v_{Ca2}}{L_{r2}}(t - t_1)
\]

(5)

\[
i_{Lo1}(t) \approx \frac{v_{Ca1} - V_o}{L_{o1}}(t - t_1)
\]

(6)

\[
i_{Lo2}(t) \approx \frac{v_{Ca2} - V_o}{L_{o2}}(t - t_1)
\]

(7)

Thus, the circulating current is decreased under the commutated state. In this step, the balance capacitor voltage \(V_{Cb} = \frac{V_{in}}{2}\).

**Step 3** \([t_2, t_3]\): At time \(t_2\), \(i_{D1} = i_{D3} = 0\) and \(D_1\) and \(D_3\) are off. Then, \(i_{Ca1} = -i_{Lo1}\), \(i_{Ca2} = -i_{Lo2}\), \(i_{r1} = i_{lm1}(t_2)\) and \(i_{r2} = i_{lm2}(t_2)\). Since \(i_{lm1}(t_2)\) and \(i_{lm2}(t_2)\) are close to zero, the circulating current is
removed. The filter inductor voltages \( v_{L1} = v_{Ca1} - V_o < 0 \) and \( v_{L2} = v_{Ca2} - V_o < 0 \). The secondary-side currents \( i_{L1} \) and \( i_{L2} \) are lessened.

**Step 4** [\( t_3, t_4 \)]: At \( t_3 \), power MOSFETS \( S_1 \) and \( S_2 \) turn off. \( C_3 \) and \( C_7 \) are discharged and \( C_4 \) and \( C_6 \) are charged. The energy on \( L_r1 \) and \( L_r2 \) can discharge \( C_3 \) and \( C_7 \) and the soft switching conditions of \( S_3 \) and \( S_7 \) are expressed in Equations (8) and (9).

\[
L_r1i_{L1}^2(t_3) \geq C_{oss}V_{in}^2/2 \tag{8}
\]

\[
L_r2i_{L2}^2(t_3) \geq C_{oss}V_{in}^2/2 \tag{9}
\]

**Step 5** [\( t_4, t_3 \)]: This step starts at \( t_4 \) when \( v_{C3} = v_{C7} = 0 \). Due to \( i_{L1}(t_4) > 0 \) and \( i_{L2}(t_4) > 0 \), the body diodes of \( S_3 \) and \( S_7 \) conduct. Then, \( S_3 \) and \( S_7 \) naturally conduct at zero-voltage switching after \( t_4 \). In this step, \( v_{ab} = -V_{cin,1}, v_{cd} = -V_{cin,2}, V_{cb} = V_{cin,2}, v_{lm1} = v_{Ca1}, v_{lm2} = v_{Ca2}, v_{Lo1} = v_{Ca1} - V_o \) and \( v_{Lo2} = v_{Ca2} - V_o \). In order to balance \( i_{L1} \) and \( i_{L2} \), the magnetic core MC is employed on the high-voltage side. Under current balance condition, \( V_{L1} = V_{L2} = 0 \). Therefore, \( v_{Lr1} \approx n_1v_{Ca1} - V_{in}/2 \) and \( v_{Lr2} \approx n_2v_{Ca2} - V_{in}/2 \). It can be observed that \( i_{Lr1}, i_{Lr1}, i_{Lo1} \) and \( i_{Lo2} \) all decrease in this step. When the secondary-side diode currents \( i_{D2} = i_{Lo1} \) and \( i_{D4} = i_{Lo2} \) at time \( t_5 \), diodes \( D_{a1} \) and \( D_{a2} \) are reverse biased. In this step, \( i_{D2} \) and \( i_{D4} \) increase from zero to \( i_{Lo1} \) and \( i_{Lo2} \), respectively and the time duration in step 5 can be obtained as:

\[
\Delta t_{45} = \frac{L_r1i_{L1,\text{min}}}{n_1V_{in}/2 - n_1^2v_{Ca1}} \approx \frac{L_r1i_{L1}}{n_1V_{in}/2} \tag{10}
\]

Since \( D_{a1} \) and \( D_{a2} \) are still conducting in this step, the duty loss is calculated in Equation (11).

\[
d_{loss} \approx \frac{L_r1i_{fsw}}{n_1V_{in}/2} \tag{11}
\]

**Step 6** [\( t_5, t_3 \)]: At time \( t_5, i_{D2} = i_{Lo1} \) and \( i_{D4} = i_{Lo2} \). Then, the secondary-side diodes \( D_{a1} \) and \( D_{a2} \) are off and \( D_{b1} \) and \( D_{b2} \) are on in this step. The inductances \( L_{1}/(n_1)^2 \) \( (L_{2}/(n_2)^2) \) and \( C_{a1} \) \( (C_{a2}) \) are resonant with frequency \( f_R = n_1/(2\pi \sqrt{L_{1}C_{a1}}) \). Since \( v_{Lo1} = v_{Ca1} \) and \( v_{Lo2} = v_{Ca2} \), \( i_{Lo1} \) and \( i_{Lo2} \) both increase in this step. In order to force \( i_{D61} = i_{D62} = 0 \) at \( t_6 \), the half resonant cycle \( 1/(2f_R) \) must be less than \( d_{loss,\text{min}}T_{sw}/2 \). The primary magnetizing voltages \( v_{lm1} = n_1(v_{Ca1} + V_o) \) and \( v_{lm2} = n_2(v_{Ca2} + V_o) \) and the primary inductor current \( i_{L1} \approx -(i_{Lo1} + i_{Ca1})/n_1 \) and \( i_{L2} \approx -(i_{Lo2} + i_{Ca2})/n_2 \).

**Step 7** [\( t_6, t_7 \)]: At time \( t_6, i_{D2} = i_{Lo1} \) and \( i_{D4} = i_{Lo2} \). Then diodes \( D_{b1} \) and \( D_{b2} \) are off. The filter inductor voltages \( v_{Lo1} \approx V_{in}/(2n_1) - V_o \) and \( v_{Lo2} \approx V_{in}/(2n_2) - V_o \) so that \( i_{Lo1} \) and \( i_{Lo2} \) increase. At \( t_7, S_2 \) and \( S_6 \) turn off.
Figure 4. Cont.
From Equation (13), the voltage gain is expressed in Equation (14).

\[
G_{dc} = \frac{V_o}{V_{in}} = \frac{1}{4n_1(1-d_{eff})}
\]
From the given input and output voltages, the turns ratio \( n \) is derived as:

\[
n = n_1 = n_2 = \frac{V_{in}}{4V_o(1 - d_{eff})}
\] (15)

Therefore, the minimum primary turns \( n_p \) and secondary turns \( n_s \) are derived in Equation (16).

\[
n_p \geq \frac{V_{Lm}d_{TSW}}{\Delta B_{\text{max}}A_c}, \quad n_s = \frac{n_p}{n}
\] (16)

where \( \Delta B_{\text{max}} \): maximum flux density range, \( A_c \): effective cross area, and \( V_{Lm} \): primary voltage.

In steady state, \( I_{Lo1} = I_{Lo2} = I_o/2 \), \( V_{Cin,1} = V_{Cin,2} = V_{C3} = V_{in}/2 \) and \( v_{S1,ds} = \ldots = v_{S8,ds} = V_{in}/2 \). If the effective duty cycle is defined, then the ripple currents \( \Delta I_{Lo1} \) and \( \Delta I_{Lo2} \) can be obtained in Equation (17).

\[
\Delta I_{Lo1} = \Delta I_{Lo2} = (V_o - V_{Ca1})(0.5 - d_{eff})T_{SW}/L_o \approx (2V_o - \frac{V_{in}}{2n_1})(0.5 - d_{eff})T_{SW}/L_o
\] (17)

If the ripple currents \( \Delta I_{Lo1} = \Delta I_{Lo2} = \Delta I_{Lo} \) are given or selected, then output inductances are achieved in Equation (18).

\[
L_{o1} = L_{o2} = L_o \geq (2V_o - \frac{V_{in}}{2n_1})(0.5 - d_{eff})T_{SW}/\Delta I_{Lo}
\] (18)

The winding turns of filter inductors \( L_{o1} \) and \( L_{o6} \) are expressed as:

\[
n_{Lo1} = n_{Lo2} \geq \frac{L_{o1}I_{Lo1,peak}}{B_{\text{max}}A_c}
\] (19)

The voltage ratings and average currents on \( D_1-D_4 \) are expressed in Equations (20)–(23).

\[
V_{D1,\text{rating}} = \ldots = V_{D4,\text{rating}} \approx V_{in}/n_1
\] (20)

\[
V_{D1,\text{rating}} = V_{D2,\text{rating}} = V_{D3,\text{rating}} \approx V_o
\] (21)

\[
I_{D1,av} = I_{D2,av} = I_{D3,av} = I_{D4,av} \approx I_o/4
\] (22)

\[
I_{D1,av} = I_{D2,av} = I_{D3,av} = I_{D4,av} \approx d_l/2
\] (23)

Based on Equation (11), the necessary inductances \( L_{r1} \) and \( L_{r2} \) are obtained as:

\[
L_{r1} = L_{r2} \approx \frac{d_{5,\text{loss}}(n_1V_{in} - 2n_1^2v_{Ca1})}{I_oT_{SW}}
\] (24)

4. Test Results

The studied circuit was verified through a prototype. In the prototype circuit, \( V_{in} \) was between 750 V and 800 V, \( V_o \) was 24 V, \( I_{o,\text{rated}} \) was 70 A, \( f_{SW} \) was 60 kHz, the effective duty cycle \( d_{eff} \) was 0.35, and the duty loss in step 5 was 0.01. Therefore, the turn-ratio and the primary-side inductances were obtained as:

\[
n = n_1 = n_2 = \frac{V_{in,\text{min}}}{4V_o(1 - d_{eff})} \approx 12
\] (25)

\[
L_{r1} = L_{r2} \approx \frac{d_{5,\text{loss}}(n_1V_{in,\text{min}} - 2n_1^2v_{Ca1})}{I_oT_{SW}} \approx 16.5 \mu H
\] (26)

In the prototype circuit, the actual magnetizing inductance, \( L_{m1} = L_{m2} = 2 \, \text{mH} \), the primary turns \( n_{1,p} \) and \( n_{2,p} \) were 48 and the secondary turns \( n_{1,s} \) and \( n_{2,s} \) were 4 with TDK EER-42 magnetic core. The maximum ripple currents \( \Delta I_{Lo} \) was assumed as 4 A. The \( L_{o1} \) and \( L_{o2} \) can be obtained in Equation (27).
\[ L_{\text{sw}} = L_{\text{on}} = (2V_o - \frac{V_{\text{in, min}}}{2n_1})(0.5 - d_{\text{eff}})T_{\text{sw}} / \Delta i_{\text{on}} \approx 10.5 \, \mu H \]  

(27)

MOSFETs SiHG20N50C with 500 V/20 A ratings were selected for \( S_1-S_8 \). MBR40100PT with 100 V/40 A ratings were selected for \( D_1-D_4 \) and \( D_{a1}-D_{b2} \). The magnetic coupling (MC) transformer \( n_p/n_s = 24 \) turns:24 turns. The adopted capacitors were \( C_{in, 1} = C_{in, 2} = 240 \, \mu F/450 \, V, C_b = 1 \, \mu F, C_{a1} = C_{a2} = 8.8 \, \mu F \) and \( C_o = 2200 \, \mu F/100 \, V \). The PSPWM integrated circuit UCC3895 was selected as a controller to control \( S_1-S_8 \).

The experimental test bench is given in Figure 5. The dc power source was using a two Chroma 62016P-600-8 programmable dc power supply connected in series to supply 800 V at the input side of the proposed circuit. The dc electronic load was a Chroma 63112A programmable dc load. The digital oscilloscope Tektronix TDS3014B was adopted to measure the test waveforms. Figure 6 illustrates the test waveforms of the gate voltages of switches \( S_1-S_4 \) in first full bridge circuit at rated power. The phase-shift angle between \( S_1 \) and \( S_4 \) depended on the input voltage. The gating voltages of \( S_5-S_8 \) in second full bridge circuit were identical to \( S_1-S_4 \), respectively. The gating voltages \( v_{\text{S1g}} \) and \( v_{\text{S4g}} \) and ac voltages \( v_{\text{ab}} \) and \( v_{\text{ad}} \) at rated power are demonstrated in Figure 7. Three-level voltages were observed on \( v_{\text{ab}} \) and \( v_{\text{ad}} \). Figure 8 illustrates the test waveforms \( v_{\text{ab}}, v_{\text{cd}}, i_{\text{Lr1}} \) and \( i_{\text{Lr2}} \) under 20% power and rated power. Two primary-side currents were well balanced with each other due to the current balance magnetic core is used to achieve current sharing. Figure 9 gives the test results of \( V_{\text{Cin1}}, V_{\text{Cin2}} \) and \( V_{\text{Cb}} \) at rated power. Split capacitor voltages were well balanced with \( V_{\text{Cin1}} = 401.6 \, V \) and \( V_{\text{Cin2}} = 398.4 \, V \). Figure 10 gives the measured waveforms of output side currents. Figure 11 provides the test waveforms of \( i_{\text{Lr1}}, i_{\text{Lr2}}, i_{\text{Lr1}}, i_{\text{Lr2}} \) under different load conditions. It is clear that \( i_{\text{Lr1}} \) and \( i_{\text{Lr2}} \) were balanced. Figure 12 provides the measured results of \( S_1 \) under 20% power and rated power. The soft switching of \( S_1 \) was succeeded from 20% power to rated power. The other switches such as \( S_2, S_3 \) and \( S_6 \) had the same characteristics as \( S_1 \). Therefore, \( S_2, S_3 \) and \( S_6 \) were also turned on with soft switching turn-on from 20% power. Figure 13 demonstrates the measured waveforms of \( S_4 \) under half and full loads. The soft switching of \( S_4 \) are realized from 50% load due to the energy on \( L_m1 \) and \( L_m2 \). Likewise, \( S_3, S_7 \) and \( S_8 \) have same characteristics as \( S_4 \) and \( S_3, S_7 \) and \( S_8 \) with soft switching turn-on from 50% power. The test efficiencies of the presented circuit are 91.7% at 20% power, 93.5% at 50% power and 92.9% at 100% power and shown in Figure 14.

Figure 7. Experimental results of $v_{S1,g}$, $v_{S4,g}$, $v_{ab}$ and $v_{cd}$ at full load (a) $V_{in}$ = 800 V and full load ($V_{Cin1}$, $V_{Cin2}$, $V_{Cb}$: 200 V/div; time: 4 $\mu$s/div). (b) $V_{in}$ = 800 V and 20% load ($V_{ab}$, $V_{cd}$: 500 V/div; $i_{Lr1}$, $i_{Lr2}$: 2 A/div; time: 4 $\mu$s/div).

Figure 8. Measured waveforms of $v_{ab}$, $v_{cd}$, $i_{Lr1}$ and $i_{Lr2}$ at 800 V input (a) 20% load ($v_{ab}$, $v_{cd}$: 500 V/div; $i_{Lr1}$, $i_{Lr2}$: 2 A/div; time: 4 $\mu$s/div) and (b) full load ($v_{ab}$, $v_{cd}$: 500 V/div; $i_{Lr1}$, $i_{Lr2}$: 5 A/div; time: 4 $\mu$s/div).

Figure 9. Measured waveforms of split voltages $V_{Cin1}$ and $V_{Cin2}$ and balance capacitor voltage $V_{Cb}$ at 800 V input and full load ($V_{Cin1}$, $V_{Cin2}$, $V_{Cb}$: 200 V/div; time: 4 $\mu$s/div).
Figure 10. Measured waveforms of the secondary-side currents in first full bridge circuit (a) 20% load ($i_{D1}$, $i_{D2}$, $i_{Lo1}$, $i_{Da1}$, $i_{Db1}$: 5 A/div; time: 4 µs/div) and (b) full load ($i_{D1}$, $i_{D2}$, $i_{Lo1}$, $i_{Da1}$, $i_{Db1}$: 20 A/div; time: 4 µs/div).

Figure 11. Measured waveforms of the secondary-side currents $i_{Lo1}$, $i_{Db1}$, $i_{o1}$ and $i_{o2}$ (a) 20% load ($i_{Lo1}$, $i_{Db1}$: 5 A/div; $i_{o1}$, $i_{o2}$: 10 A/div; time: 4 µs/div) and (b) full load ($i_{Lo1}$, $i_{Db1}$, $i_{o1}$, $i_{o2}$: 20 A/div; time: 4 µs/div).
**Figure 12.** Measured waveforms of the leading-leg switch $S_1$ at 800 V input (a) 20% load ($v_{S1,g}$: 10 V/div; $v_{S1,d}$: 200 V/div; $i_{S1}$: 1 A/div; time: 2 μs/div) and (b) full load ($v_{S1,g}$: 10 V/div; $v_{S1,d}$: 200 V/div; $i_{S1}$: 2 A/div; time: 2 μs/div).

**Figure 13.** Measured waveforms of the lagging-leg switch $S_4$ at 800 V input (a) 50% load and (b) full load ($v_{S4,g}$: 10 V/div; $v_{S4,d}$: 200 V/div; $i_{S4}$: 2 A/div; time: 2 μs/div).
5. Conclusions

A parallel dc/dc converter was proposed and investigated to achieve the main benefits of balanced input split voltages, load current sharing and reduced circulating current loss. Input split voltage balance was realized using a balance capacitor to automatically charge/discharge split capacitors in every switching cycle. The current sharing of two series full bridge circuits was achieved using a magnetic core. Passive circuits were employed on output side to decrease primary circulating current at commutated state. However, the proposed converter was out of work under power switch failure. Therefore, some bypass circuits may be added in the circuit to protect the converter from damage. This protection procedure is the next study case to further improve the circuit reliability. The theoretical analysis was well supported by the test waveforms of a prototype.

Author Contributions: B.-R.L. designed the project and was responsible for writing the paper.

Funding: This research is funded by the Ministry of Science and Technology, Taiwan, grant number MOST 107-2221-E-224-013.

Acknowledgments: This research is supported by the Ministry of Science and Technology, Taiwan, under contract MOST 107-2221-E-224-013. The author would like to thank Mr. Wei-Po Liu for his help to measure the circuit waveforms in the experiment.

Conflicts of Interest: The author declares no potential conflict of interest.
