**Abstract:** *Selaginella tamariscina* (Beauv.) has been used for traditional herbal medicine for treatment of cancer, hepatitis, and diabetes in the Orient. Numerous bioactive compounds including alkaloids, flavonoids, lignans, and selaginellins have been identified in this medicinal plant. Among them, selaginellins having a quinone methide unit and an alkylphenol moiety have been known to possess anticancer, antidiabetic, and neuroprotective activity. Although there have been studies on the biological activities of selaginellins, their modulatory potential of cytochrome P450 (P450) and uridine 5′-diphosphoglucuronosyltransferase (UGT) activities have not been previously evaluated. In this study, we investigated the drug interaction potential of two selaginellins on ten P450 isoforms (CYP1A2, 2A6, 2B6, 2C8, 2C9, 2C19, 2D6, 2E1, 2J2 and 3A) and six UGT isoforms (UGT1A1, 1A3, 1A4, 1A6, 1A9 and 2B7) using human liver microsomes and liquid chromatography-tandem mass spectrometry. Selaginellin and selaginellin M had high inhibitory potential for CYP2C8-mediated amodiaquine O-demethylation with IC50 values of 0.5 and 0.9 μM, respectively. Selaginellin and selaginellin M also showed medium inhibitory potential against CYP2C9, UGT1A1, and UGT1A3 (1 μM < IC50 < 5 μM). These two selaginellins had low inhibitory potential against CYP1A2, CYP2A6, CYP2E1, and UGT1A6 (IC50 > 25 μM). This information might be helpful to predict possible drug interaction potential of between selaginellins and co-administered drugs.

**1. Introduction**

*Selaginella tamariscina* (Beauv.) which belongs to Selaginellaceae, has been traditionally used in treating blood in excrement, hematuria, inflammation, chronic hepatitis, and hyperglycemia in the Orient, especially in China [1,2]. A number of alkaloids, flavonoids, lignans, selaginellins, phenolics, and terpenoids were reported as chemical constituents of *S. tamariscina* [3]. Among these constituents, selaginellins are another group of polyphenolics with a p-quinone methide unit and an alkynylphenol carbon skeleton [4]. Pharmacological studies demonstrate that selaginellins have been known to have anticancer [5–7], antidiabetic [8,9], antimicrobial [10,11], antioxidant [12,13], antihyperlipidemic [13], and neuroprotective [14] activities.
Use of botanical drugs to prevent common disease is on the rise among the global population [15]. Since botanical drugs share the same drug metabolizing enzymes with commonly used commercial drugs, the potential for herb–drug interaction is substantial [16]. Several medicinal herbs and foods, including St. John’s wort [17] and grapefruit juice [18] as well as their active constituents (hyperforin [19] and bergamottin [20]) have been reported to cause severe drug interactions. Undoubtedly, the early evaluation of herb–drug interactions is necessary to prevent potential dangerous clinical outcomes.

Modulation of drug-metabolizing enzymes is one of the important causes of drug–drug or herb–drug interaction. Among the numerous drug-metabolizing enzymes, cytochrome P450s (P450s) and uridine 5′-diphosphoglucuronosyltransferases (UGTs), which are responsible for the metabolic clearance of 90% of commercial drugs, have been shown to play key roles in drug metabolism and drug interactions [21]. For example, bergamottin is reported to increase the blood concentration of drugs through inhibition of hepatic CYP3A activity, thereby enhancing the toxicity of drugs such as atorvastatin, felodipine, and verapamil [22]. Pre-treatment with psoralidin, which has inhibitory potential against UGT1A1-mediated SN-38 glucuronidation (Ki = 5.8 μM), was shown to increase the toxicity of irinotecan [23]. Accordingly, P450- and UGT-mediated drug interactions are even more critical.

Therefore, modulation of selaginellins on P450 and UGT activities may result in potential increase of the systemic exposures of co-administered drugs. To the best of our knowledge, however, no previous study has reported the modulatory effects of selaginellins against human P450 and UGT activities. Here, we investigated the inhibitory potential of two selaginellins (Figure 1) on ten P450- and six UGT-isoform activities in human liver microsomes (HLMs) using cocktails of P450 or UGT probe substrates to evaluate the possibility of drug interactions of selaginellins.

2. Results and Discussion

In the present study, we investigated the inhibitory effect of two selaginellins against ten cytochrome P450 isoforms and six UGT isoforms using human liver microsomes (Figure 2). The results showed that selaginellin inhibited most of the P450 and UGT isoforms tested in a concentration-dependent manner. The inhibitory potential of selaginellins is categorized into high (IC₅₀ < 1 μM), medium (1 μM < IC₅₀ < 10 μM), and low (IC₅₀ > 10 μM) classes based on Krippendorff’s criteria [24].

Selaginellin and selaginellin M had high inhibitory potential for CYP2C8-mediated amodiaquine O-demethylation (Table 1), respectively, indicating that herbal drugs containing selaginellins may be used carefully with drugs metabolized by CYP2C8, such as anti-cancer drugs (paclitaxel and sorafenib), anti-diabetics (repaglinide), and diuretics (torsemide) in order to avoid drug interactions [25]. The inhibitory potential of these two selaginellins on CYP2C8 (IC₅₀ < 1 μM) were lower than that of troglitazone (IC₅₀ = 2.3 μM [26]) and quercetin (IC₅₀ = 7.2 μM [27]). Their inhibitory potentials, however, were less potent than montelukast, an strong CYP2C8 inhibitor (IC₅₀ = 0.019 μM [28]).
Two selaginellins also showed medium inhibitory potential on CYP2C9-catalyzed tolbutamide hydroxylation, CYP2J2-catalyzed astemizole O-demethylation, UGT1A1-catalyzed SN-38 glucuronidation, and UGT1A3-catalyzed chenodeoxycholic acid glucuronidation activities (IC50 < 5 μM). CYP2C8, CYP2C9, and CYP2J2 metabolize approximately 4.7, 12.8, and 3% of clinically used drugs (n = 248), respectively [29]. UGT1A1 also metabolizes approximately 17.3% of drugs (n = 237) which have glucuronidation as a clearance mechanism [30,31]. Therefore, the inhibitory effect of selaginellins might be important for producing potential herb–drug interaction with drugs which undergo CYP2C8, CYP2C9, CYP2J2, and UGT1A1-mediated biotransformation; such drugs include glipizide, irinotecan, losartan, paclitaxel, tolbutamide, and warfarin [32].

The effects on CYP1A1, CYP2A6, CYP2E1, and UGT1A6 activities were assumed to be a negligible (IC50 > 25 μM) (Table 1). These findings suggest that clinical interactions between these compounds and CYP1A1, CYP2A6, CYP2E1, or UGT1A6 would not occur.

Selaginella tamariscina (Beauv.) Spring has been used for centuries as a Traditional Chinese Medicine to treat various human diseases, including inflammation, human cancer, and hyperglycemia [33]. Therefore, it might be used with anticancer or antidiabetic drugs which are metabolized by CYP2C8 (paclitaxel), CYP2C9 (tolbutamide), or UGT1A1 (irinotecan) [32]. Selaginellins should be used carefully with these drugs to avoid drug interactions in cancer and diabetic patients.

3. Material and Methods

3.1. Reagents

Alamethicin, β-Nicotinamide adenine dinucleotide phosphate (NADP+), chenodeoxycholic acid, trifluoperazine, N-acetylserotonin, mycophenolic acid, naloxone, naloxone-β-D-glucuronide, uridine 5'-diphosphoglucuronic acid (UDPGA), glucose-6-phosphate (G6P), glucose-6-phosphate dehydrogenase (G6PDH), terfenadine (internal standard (IS) for P450 assay), estrone-β-D-glucuronide (IS for UGT assay), phenacetin, dextromethorphan, coumarin, chlorozoxazone, bupropion, astemizole, amodiaquine, acetaminophen, hydroxybupropion, hydroxycoumarin, hydroxychlorzoxazone, and N-desethylamodiaquine were purchased from Sigma-Aldrich (St. Louis, MO, USA). Tolbutamide, omeprazole, midazolam, dextorphpan, 1'-hydroxymidazolam, hydroxyomeprazole, hydroxytolbutamide, N-acetyl serotonin-β-D-glucuronide, chenodeoxycholic acid-24-acyl-β-glucuronide, mycophenolic acid-β-D-glucuronide, SN-38, and SN-38-glucuronide were obtained from Toronto research Chemicals (Toronto, ON, Canada). Solvents were LC-MS grade (Fisher Scientific Co., Pittsburgh, PA, USA) and the other chemicals were of the highest quality available. Pooled human liver microsomes (HLMs, H2630, mixed gender) were purchased from XenoTech (Lenexa, KS, USA). Selaginellins: Selaginellin and selaginellin M were isolated from Selaginella tamariscina (Beauv.) which was collected at Hon Ba Nature Reserve, Khanh Hoa province, Vietnam. The two compounds were purified and examined by HPLC to get 95% purity. Their chemical structures were identified by analyzing their NMR data which were in good agreement with those published in a previous report [8].
3.2. Microsomal Incubation

3.2.1. Inhibitory Effects of Selaginellins on P450 Activity

The inhibitory effects of two selaginellins on the metabolism of ten P450 probe substrates were evaluated using previously reported method with minor modification [27]. Phenacetin O-deethyelase, coumarin 7-hydroxylase, bupropion 4-hydroxylase, amodiaquine N-deethyelase, tolbutamide 4-hydroxylase, omeprazole 5-hydroxylase, dextromethorphan O-demethylase, chlorzoxazone 6-hydroxylase and midazolam 1′-hydroxylase activities were determined as probe activities for CYP1A2, CYP2A6, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, CYP2E1 and CYP3A2, respectively, using substrate cocktail incubation and tandem mass spectrometry (Table 2). Selaginellins were dissolved in methanol. The final concentrations of organic solvent (methanol) for the cocktail incubation conditions in all experiments were 1.0% (v/v). In brief, the incubation mixtures containing pooled HLMs (0.25 mg/mL, H2630, Xenotech), P450 probe substrate cocktail, and inhibitor (0, 0.5, 2, 5, 20 and 50 μM) were preincubated at 37 °C for 5 min. The reaction was initiated by adding of the NADPH generating system (3.3 mM G6P, 1.3 mM β-NADP+, 3.3 mM MgCl₂, and 1 unit/mL G6PDH) followed by incubation for 15 min at 37 °C. Next, each incubation was stopped by addition of 50 μL ice-cold acetonitrile containing terfenadine (IS). After mixing and centrifugation, aliquots were analyzed by liquid chromatography-tandem mass spectrometry (LC-MS/MS) as previous described [27,34]. The CYP2J2 inhibitory effects of two selaginellins were also evaluated in pooled HLMs using previously reported method [35,36]. In brief, the incubation reaction mixtures contained 0.25 mg/mL HLMs, astemizole (1 μM) and inhibitor (0.5–50 μM) in 0.1 mM phosphate buffer (pH 7.4). The reaction was initiated by the addition of NADPH-generating system and further incubated for 15 min. After reaction termination with cold acetonitrile containing 5 ng/mL terfenadine and centrifugation, aliquots were injected into a liquid chromatography-tandem mass spectrometry system (LC-MS/MS) as described previously [35] (Table 2). All microsomal incubations were performed in triplicate.

3.2.2. Inhibitory Effects of Selaginellins on UGT Activity

The inhibitory effects of two selaginellins on the metabolism of six UGT probe substrates were evaluated using previously reported method with minor modification [34]. In brief, HLMs (0.25 mg/mL) were activated by incubation in the presence of alamethicin (25 μg/mL) for 15 min on ice. After the addition of UGT isoform-selective substrates and selaginellins (0, 0.5, 2, 5, 20 and 50 μM) the final concentrations of organic solvent (methanol) for the cocktail incubation conditions were 1.0% (v/v). The incubation reaction mixtures were pre-incubated for 5 min. The reaction was initiated by the addition of 5 mM UDPGA and further incubated for 60 min. All reactions were terminated by adding ice-cold acetonitrile containing estrone glucuronide (IS). After mixing and centrifugation, aliquots were injected into a LC-MS/MS as described previously [34] (Table 2). All microsomal incubations were performed in triplicate.

3.3. Data Analysis

The IC50 values (concentration of the inhibitor causing 50% inhibition of the original enzyme activity) were calculated using WinNonlin software (Pharsight, Mountain View, CA, USA): percentage of control activity = 100 × [1 – (I/(I + IC50))], where I is the inhibitor concentration, and IC50 is the inflection point on the curve [34].
